NEW JERSEY HEALTH STATISTICS 1984

INTRODUCTION

Health Statistics is one of 12 Volumes in the Department of Health's Data Handbook series. The scope and coverage of Health Statistics currently includes highlights, historical perspective, natality, mortality, marriages, divorces, morbidity, accidents, fertility, abortions, population, and vital statistics gross summary. A section of technical notes is included that explains statistical methods used and data limitations; a list of definitions and a description of Rates, Ratios, Proportions and Indices are also covered.

Only State and County statistics are presented with selected municipality (MCD) data if appropriate because of size limitations. A new section on Vital Statistics Gross Summary presents Municipality data for population, births, deaths and marriages. Additional Vital Statistics at the MCD level are available for inspection and use in the Trenton central offices of the Department. Copies of specific MCD information have been supplied to local Health Officers and both County and MCD information have been placed in the NJ/DOH Northern and Southern regional offices.

Births, deaths, marriages, and fetal deaths, occurring in 1984 are statistics presented in this Volume. They were obtained from Certificates filed with the State Registrar prior to August 1, 1985. Through a reciprocal arrangement between states, copies of birth, death, and fetal death certificates involving out-of-state occurrences are interchanged. Thus, the resident birth, death and fetal death rates shown in the report include all events involving residents of the State of New Jersey irrespective of place of occurrence. Marriage statistics, however, are treated differently. A tabulation is made of all marriages occurring within the State irrespective of the residence of either party. Copies of marriage certificates are not interchanged between states as such a procedure would prove impractical (see Technical Notes).

The Tuberculosis Control, Sexually Transmitted Disease, and the Communicable Disease Control programs are responsible, by law, for maintaining confidential files on "reportable diseases." Statistics maintained are tabulated by the Center for Health Statistics annually and are included in the report in order to allow the user to develop a more complete profile of health of the residents of the State.

The newly formed AIDS unit is presently developing a data base file which will eventually contain all identified AID cases within the State. Comparable statistics on the number of reported cases within New Jersey or by state of residence are not available at this time. Health Statistics for 1985 will contain historic and current data. All requests for statistics related to AIDS should be directed to the New Jersey AIDS program.

Morbidity data as related to hospitalization were obtained from Patient Discharge Abstract Summaries. Discharge Abstracts are submitted to the Department quarterly for use in the Hospital Case-Mix and Diagnosis Related Groups programs. Discharge Abstracts are received for all patients upon hospital discharge regardless of the patient's disposition or place of residency. Accident reporting is derived from the Death Certificates and is presented in two parts. The first comprises aggregated Accident Deaths related only to New Jersey residents and the second presents a detailed statistical listing of all deaths occurring within the State regardless of place of residency by category and type.

The Office of Demographic and Economic Analysis, Department of Labor, is assigned responsibility by the Governor of the State to provide Official State Annual Estimates of Population for all 567 municipalities and 21 counties. These estimates are periodically revised to reflect the latest information available with respect to births, deaths and migration. The revised July 1, 1983 estimates, released in September 1985 were used in developing the Vital Statistics rates shown in this report. All rates for prior years were recalculated based on the Revised Population estimates. Age, sex and race specific estimates for 1984 were developed by the Center for Health Statistics, based on the "Proportionate Share Techniques" using the 1980 census data controlled to the July 1, 1983 revised estimates. The age, sex, and race data shown in this report are to be considered as crude estimates and should only be used for statistical purposes. The population for 1984 was assumed to have the same age, sex, and race distribution as existed in the 1980's based on Census counts.

Back issues of the Health Statistics for 1979 through 1983 are available as long as supplies last and can be obtained by written request to the Center for Health Statistics. Vital Statistics data and reports for the periods 1877 through 1983 are maintained as Reference by the N.J. State Library, the New Jersey Department of Health Library, and the Center for Health Statistics. Inquiries regarding the contents of this report or information concerning other Volumes in the New Jersey Health Data Handbook series should be addressed to:

How to Use This Report

Overview

The purpose of the New Jersey Health Statistics Annual Report is to provide in health data related to vital statistics that are compiled and maintained by the New Jersey Department of Health. The Annual Report is divided into four sections and designed to serve as a Vital Statistics reference document for 1984 data. Only those data that are most requested have been included in this document. Additional information is available through the Center for Health Statistics, New Jersey Department of Health. The user of this Annual Report is advised that the data herewith contained is for the calendar year 1984 and is subject of change if corrections or additional information becomes available.

Page Numbering System

For quick identification and easy access, each section of the report has been given a number. A "TAB" page numbering system has also been used so that the user can rapidly locate subdivisions within each section. All major categories within Section I have been cross-indexed and included in Section IV--Index. All sections and subdivisions have been printed on yellow paper for easy location.

Additions and Revisions

The report has been developed in "loose-leaf" format to permit additions and revisions. All holders of the report registered with the Center for Health Statistics will automatically receive copies of revisions and/or additions when released. If a three-ring binder has not been supplied, the holder is advised to place the document in a three-ring binder. All pages have been "three-hole" punched. All sections can be located by determining the TAB page in the Table of Contents and then flipping through the document to find the appropriate location. To register, please complete and supply to the Center for Health Statistics the following information:

-----NOTE-----

This HIGHLIGHTS--Summary Report presents an overview of the 1984 HEALTH STATISTICS REPORT. HIGHLIGHTS has been prepared containing data for state, county and selected places of residence. The 1984 HEALTH STATISTICS REPORT in its new expanded format provides detailed data on each of the major health categories in the Vital Statistics area. If you desire additional information concerning the NJ/Health Statistics provided in this Report, please address your inquiries to:

NEW JERSEY HEALTH STATISTICS

HIGHLIGHTS

1984

POPULATION

New Jersey reached a 1980 population total of 7,364,823 persons ranking it 9th in the nation. With an average of 986.2 persons per square mile it continued to retain its position as the most densely populated of the states. The 1980 Census indicated that New Jersey's population continues to remain relatively young with the median age at 32.2, slightly higher than the U.S. level of 30.1. The percentage of population 65 and older increased between 1970 and 1980 at a rate of 2 ½ times the national figure--a rate of growth exceeded in only four states. Projections indicate a continued increase in the percentage of older population in the State. The July 1, 1984 revised estimate of 7,515,000 indicated only a slight increase in population growth for the State as a whole with a total increase of 150,000 since the 1980 census. The 1983 revised estimate is 7,464,000.

INCOME

New Jersey's per capita personal income of \$15,440 for 1984 was 21% higher than the national level of \$12,789 and ranked New Jersey 3rd among the states, up from a rank of 6th in 1983. Nine percent of New Jersey families are below poverty level, placing New Jersey 44th among the states. Per capita disposable personal income has progressively increased since the Census and by 1984 has reached the level of \$13,179 (compared to \$10,951 for the U.S.).

MARRIAGE/DIVORCE

The State's marriage rate has continually fluctuated annually since 1946 and has moved upward again to reach its highest point since the WW-II level. The divorce rate on the other hand has shown a steady decline. For every 100 marriages performed in New Jersey in 1984, 45.4 divorces were granted, a ratio of 2 to 1.

...Low Birth
Weight

The incidence of low birth weight babies in New Jersey decreased slightly from the 1983 level of 7.1% to 7.0% in 1984. The incidence in the State remains slightly higher than nationally, and is highest for younger and older women and lowest for women between the ages of 25 to 34.

...Multiple
Births

There were 2,179 live births in multiple deliveries. Of these, 2,124 (97.5%) were twins with 55 (2.5%) being triplets and others.

MORTALITY

New Jersey with an older population age structure than the U.S., has a crude death rate above the national figures; age adjustment of the rates reveal a mortality closer to that experienced nationally. The New Jersey crude mortality rate per 1,000 population for 1984 was 9.2 (U.S. rate 8.7). Total deaths in New Jersey registered 68,944, an increase of 318 over the 1983 level of 68,626.

...Life Expectancy

The expectation of life at birth reached a new U.S. high in 1983 (and remained at that level in 1984)--an estimated 74.7 years for the total population. Life expectancy at birth for New Jersey residents was at 74.0 (in 1980) and New Jersey was the 23rd State when ranked on this indicator. Life expectancy for New Jersey females is 77.4, while males have an expectancy of 70.5 years (based on 1980 information).

...Leading Causes

Heart disease, cancer, cerebrovascular diseases, and accidents continue for 1983 to be the leading causes of death in New Jersey. Mortality from heart disease and cancer is higher in New Jersey than nationally, but the accident rate is 12.2% lower compared to the national level. (US = 40.1 NJ = 27.9). Overall, mortality in the State decreased in 1984 for heart disease, chronic liver disease and cirrhosis, cerebrovascular diseases and accidents, while increasing for cancer (very slightly from 221.6 to 221.7), influenza/pneumonia, and suicide. Accidents were the leading cause of death for those between the ages of 1 to 24. Suicide and homicide ranked next as causes of death for those between 15 to 24 years of age.

ABORTION

A total of 31,236 New Jersey resident women obtained legal induced abortions in 1984, a 26.4% increase since 1983. Of those obtaining abortions 26.1% were under 20 years of age, and 55.7% were in the 20-29 year group. Three-fourths (75.5%) were unmarried, 53.1 had no living children, while 57.0 had no previous abortions, and 51.4% obtained the abortion prior to the 9th week of gestation.

BIRTHS

New Jersey experienced an increasing birth rate between 1976 and 1984 and currently ranks 46th lowest birth rate per 1,000 people among the states. The national rate for 1984 was recorded at 15.7%. The New Jersey rate was 13.4 or 22% below the national level. Resident births in the State were recorded at 100,950 and were at the highest level since 1972. The 1984 level represented an increase of 2.2 percent over 1983.

...Age of Mother

Births were higher in New Jersey for all women over the 1983 level. Women in their teens show a decrease of 575 or 5.3% while the 20-34 showed an increase of 2,113 births or 2.6% and women 35+ showed an increase of 642 births or 9.1%.

...Live Birth Order

Thirty-three percent of births to New Jersey residents were first order births. The general long-term trend has been toward a greater percentage of higher order births in the State.

...Births to Unwed Mothers

A level of 22.2% of all live births in New Jersey during 1984 were to unwed mothers. The ratio of births to unwed mothers is highest for teenagers. It is for mothers in the age group of 20 and older that the ratio in New Jersey exceeds the national level.

INFANT MORTALITY

In 1984, infant deaths reported at 1,090 dropped by 25 from the 1983 level of 1,115. The 1984 infant mortality rate of 10.8 per 1,000 births was also down from the 1983 rate of 11.3. Both the neonatal death rate and infant death rate have been on a downward trend since the Department started collecting statistics in 1879. The year 1984 was no exception, showing a further decrease and a lower rate per 1,000 births in the total number of infant deaths reported.

MATERNAL MORTALITY

New Jersey's maternal mortality rate has consistently been lower than the U.S. maternal mortality rate, but it is fluctuating. In 1984 an increase over 1983's number of 5 deaths was observed in maternal mortality which reached a level of 11 (the same level as in 1982).

FETAL MORTALITY

A total of 1,062 resident fetal deaths were reported in 1984. The 1984 level was the highest since 1977. The State's fetal death rate, however, has consistently been dropping over the last fifty years and for 1984 was at the rate of 10.5 (up from 8.5 in 1983).

COMMUNICABLE DISEASES:

...Gonorrhea

The number of reported cases in the State decreased from the 1983 level of 22,075 to 20,101 in 1984. A drop of 1,974 cases (or 8.9%).

...Syphilis

New Jersey's case rate for all stages of syphilis has decreased from 28.1 cases per 100,000 population in 1983 to 26.5 in 1984.

...Tuberculosis

The State's incidence for tuberculosis has increased slightly from 891 cases in 1983 to 935 in 1984 (or 4.9%). Clinically active cases decreased during the same period from 809 to 790 cases (or 2.4%).

...Other

In 1984, 23 cases of rubella were reported increasing significantly from 3 cases reported in 1983. Hepatitis Type A increased by 20.2% from 546 to 656 cases, while Type B decreased (by 10.4%). After a minor outbreak of measles in 1981 (61 cases) the number reported dropped to 18 in 1982 to 3 in 1983, and rose slightly to 7 in 1984.

ACCIDENTS

Total accidental deaths by occurrence in New Jersey in 1984 continued to drop and reach their lowest recorded level since 1970, recording 2,265 deaths. Motor Vehicle accidents remained as the major cause, accounting for almost one-half of all accident deaths in each of the years. Motor Vehicle deaths decreased from 1983 with pedestrians accounting for one-fourth of all motor vehicle deaths. Falls and fires accounted for almost two-thirds of the "In-home" category. Drownings and falls responsible accounted for almost one-half of the Nonmotor Vehicle deaths that occurred outside the home. The 1984 ranking of residential deaths by class of accident in any location or specific setting was: motor vehicle, falls, fires, drownings, and poisonings.

Note: Clinically active cases are those with a culture positive for *M. tuberculosis* or those on two or more anti-tuberculosis drugs. The count includes those with a previous episode of tuberculosis who have developed disease again if more than 12 months have elapsed since they were discharged from supervision. Nonclinically active cases were not included in the count if medication was not prescribed.

Rates for State Institutions and Military Posts are not computed due to lack of population base.

HISTORICAL PERSPECTIVE

INTRODUCTION

The Historical Perspective as presented in this report presents an overview of the United States and New Jersey Vital Statistics trends, as primarily related to births and deaths. No attempt has been made to expand the coverage into other areas of vital statistics such as morbidity or abortion. A series of tables have been included that give historical aggregated data for selected items.

STATISTICAL OVERVIEW

U.S. TRENDS

The U.S. population reached 226.5 million as of April 1, 1980. Recent projections indicate that the population will increase to a level of 249.7 million by 1990 and to 268.0 million by the year 2000. These levels are based on the assumption that the U.S. couples will have an average of two children.

The rate of population growth has slowed substantially since the 1950's. This has primarily been a result of the decrease in the annual number of births from a level of 4.3 million in the late 1950's to 3.7 million in 1983. If growth continues at the 1970-80 average annual rate, according to the U.S. Census, the population will double in size in about 85 years. In other industrialized countries with slower growth rates than the United States, such as the German Federal Republic, England and Wales, it will take as many as 347 years for the population to double. In the lesser developed countries such as Mexico, with higher rates of growth, the population will double in about 17 years.

The number of people 65 years of age and over in the U.S., by the end of the century, is projected to increase by about 9 million, or from 10.7 percent of the population to 12.2 percent. Since the elderly are less healthy and utilize more health services than younger people, the increasing number of elderly portends increased demand for health services.

Birth rates in general have steadily decreased since the late 1950's, with women having their first child at a later age than in the past. From 1972 to 1976, rates of the first birth increased for women in age groups 25-29 and 30-34 and decreased for women 20-24 years of age. Birth rates for young teenagers between 15-17 did not begin to drop until the early 1970's, unlike the rates for older teenagers, 18-19, which followed the patterns similar to women 20-24 years of age.

U.S. statistics show that teenage mothers are likely to face negative educational and income consequences when compared with older mothers. For each year a high school student postponed her first birth, she can expect to complete almost an additional year of schooling.

After a rapid decline from 1960 to 1976, fertility rates in the U.S. for women 15-44 years of age have been gradually increasing, reaching 68.4 births per 1,000 in 1980 and dropping to 66.0 in 1984. This trend is partly because of postponed births as witnessed by postponed marriages. Between 1982 and 1983 a 2.4 percent decrease in the estimated number of births was observed, in contrast to the approximately two percent increase observed both between 1981 and 1982 and between 1983 and 1984.

The estimated live births in 1982 was the largest number observed since 1970. The birth rate for 1982 at 16.0 live births per 1,000 population was at its highest level since 1971 (17.2). The birth rate of 15.7 for 1984 was pretty comparable to the previous year (15.5).

This trend will probably continue in the future. For example, based on lifetime birth expectations of married women 18-34 years of age in the United States, an average of 2.2 lifetime expected births was estimated in 1983 compared with 3.1 in 1967. According to new projections prepared by the U.S. Bureau of the Census, the number of women in the childbearing ages will increase by about 1 percent annually through 1985. The annual number of births therefore should continue to rise, although slightly, unless there are offsetting declines in age-specific birth rates. Between 1985 and 1990, the number of women aged 15-44 years is expected to stabilize with annual increases of less than 1 percent. Slight declines in this population are anticipated between 1990 and 2000. Overall, life expectancy at birth continued to increase through 1984, reaching a new high of 74.7 years for the total population. Record highs were also established for each race-sex group and reached 71.0 years for men and 78.1 years for women of all races.

NEW JERSEY TRENDS

Future population in New Jersey is not projected to grow as fast as the nation as a whole. This is understandable with its present population density level of 1012.6 persons per square mile (as of July 1, 1985) and its declining industrial employment base. New Jersey is the most densely populated state in the nation and the first state to pass a thousand persons per square mile. The New Jersey Department of Labor recently projected that by the year 2000 the State's population would reach the 8.5 million mark and 9.2 million is anticipated by July 1, 2020. This annual growth rate of about 0.6% is higher in this decade than the 0.3% per annum growth that took place over the 1970-80 period.

The growth that will occur according to what the statistics indicate, will be due partially to an assumed increase in the number of births and projected in-migration from employment growth. The increase in births is based on what appears to be the result of the relatively large numbers of women in the childbearing ages between 15-44 years of age. Strong employment growth, based on trend data, is indicated in several counties and also further additions to the population from Atlantic City hotel-casinos indicates a level of about 14% increase by the year 2000.

Looking back, we find that during the fifties and the sixties New Jersey's population grew much faster than the nation, despite overall lower birth rates and higher death rates. The rapid growth in the State's population was attributed to a large scale net in-migration that took place mostly from the neighboring states of New York and Pennsylvania. In the 1970's, however, New Jersey registered an almost stationary 2.7 percent population growth as compared to 11.4 percent average rate for the United States. The reversal of the trend that took place during the seventies was almost entirely because of a net out-migration.

The State's population growth was in suburbia and concentrated more in the northeast and southwest counties than in the rural or shore areas. The urban areas, in contrast, experienced a population decline from 1970 to 1980 as the loss of the State's industrial base had its impact. Nine out of ten of the State's residents, an overwhelming majority, however, continue to live in the major urban centers of the State.

The racial composition, age distribution, and other population characteristics did not change and are similar to those of the United States. Two major differences, however, have been observed: 1) the rapid growth of the State's minority population which now is twice that of the national rate; and 2) the marriage and divorce rates which both have, during the past decade, substantially dropped lower than the national average.

The New Jersey vital statistics trends over the years have closely paralleled those of the nation as a whole. The gap, however, for births increased during the decade of the 70's indicating a slower annual rate in New Jersey than nationally. Around 1977, a stabilization occurred even though the rate was considerably lower in New Jersey than nationally. Mortality trends present a different picture. In 1960, the State's mortality rate per 1,000 population was less than that of the nation. In 1967, an increase started nationally which in turn pushed the New Jersey rate below that of the nation. While the difference was not great, the rate remained below the national level until 1975 when New Jersey's crude mortality

rate exceeded that of the United States. A higher crude mortality rate has continued since that time, producing a steady widening of the gap. Part of the reason for this gap is the proportion of the population aged 65 and above is a larger share of the population in New Jersey: 12.5 percent of New Jersey's population was 65 years or older in 1984 compared to 11.9 percent nationally. In 1980 the elderly represented 11.7 percent of New Jersey's population and 11.3 percent of the nation's population; therefore New Jersey's proportion of elderly is increasing faster than that of the nation.

A closer look at the birth rates in both New Jersey and the United States shows a substantial decline over the past 30 years. Since 1980, however, the birth rate has had a slight increase. The National Rate for 1981 rose to a level of 15.8 and the 1982 rate reached 15.9, then declined to 15.5 in 1983 and rose slightly to 15.7 in 1984. In New Jersey, the 1981 level was 13.0 with the 1982 and 1983 rates both at a level of 13.2, and in 1984 the level rose to 13.4. The birth rate represents the number of births per 1,000 population.

The New Jersey birth rate, at its peak in 1947, reached 23.9 births per 1,000 population. Even with the seesaw effect that occurred, 10 years later the rate dropped only 1.3 to a level of 22.6 by 1957. The downward slide reached 16.8 in 1967 and ten years later in 1976 a low of 12.3 was recorded. The upward push started in 1977 and by 1984 a level of 13.4 per 1,000 population had been attained.

The fertility rate which gives the ratio of live births per 1,000 women between the childbearing age of 15-44 is considered a better indication of actual birth trends.

The fertility rate for New Jersey in 1970, calculated as the number of total live births for women aged 15-44 per 1,000, was 81.2 for the State as compared to 82.6 births per 1,000 for the nation. With the downward trend in population, out-migration and a lower birth rate, it is an obvious calculation that the fertility rate also has to be affected. By 1975 the fertility rate for New Jersey had dropped to 56.6 and the U.S. down to the level of 65.8. In 1980, the New Jersey rate stabilized leveling at 57.0 per 1,000 births. In 1984, a slight movement brought the rate to 57.4. During the same time period (1980 to 1984) the fertility rate in the United States dropped from 68.4 to 66.0.

Perinatal mortality is a composite statistic used to measure the critical period of human development just prior to birth and shortly thereafter. Perinatal mortality, as presented in this report includes fetal deaths plus neonatal deaths (infant deaths under 28 days of age). Since 1947, the start of computing perinatal mortality rate in New Jersey, the rate has decreased by nearly 250 percent, dropping from 41.4 to 16.0 deaths per 1,000 live births plus fetal deaths in 1983. An upturn of 10.6 percent was observed between 1983 and 1984 when the perinatal mortality rate reached 17.7 per 1,000 live births. Over the last twenty-five years maternal deaths have been reduced dramatically and may in the near future be almost entirely eliminated if the present trend continues. Over the last five years (1980 to 1984), however, a slight fluctuation has occurred in the New Jersey rate, registering 0.5, 0.7, 1.1, 0.5, and 1.1 respectively.

Table 6 shows time trends in rates of homicide and suicide, TB cases and deaths and syphilis and gonorrhea cases. Homicide rates have risen sharply in New Jersey over the decades observed (1940 to 1980) from 1.7 per 100,000 population to 7.2. A decrease of 18.9 percent was observed between the 1982 rate

of homicide (7.4 per 100,000) and the 1983 rate (6.0 per 100,000). In 1984 the homicide rate was 5.8 per 100,000 population. Suicides also dropped between 1982 and 1983 by 4.9 percent to a rate of 7.7 per 100,000 population, and then increased by 11.7 percent to a rate of 8.6 per 100,000 population in 1984.

TB cases rose by almost 5 percent between 1983 and 1984 to 935. The 1984 case fatality ratio was 74.9 per 1,000 (compared to 62.9 per 1,000 in 1983).

Syphilis* incidence rates in New Jersey decreased from 28.0 per 100,000 in 1983 to 26.9 per 100,000 in 1984 or 4.1 percent and remained below the rate for the nation (of 29.8 in 1984). The gonorrhea incidence rate of 270.8 per 100,000 in 1984 was the lowest it has been in five years, and is far below the national rate of 374.8 in 1984.

Deaths by major cause group can be compared for New Jersey and the United States in 1984 as shown in Table 7. New Jersey's ranking by cause group is the same as that for the nation with the leading causes being heart diseases, malignancies, cerebrovascular diseases and accidents (accounting for 73.7 percent of the deaths in New Jersey). While New Jersey's death rates for heart diseases and malignancies are higher than those for the nation, the reverse is true with respect to accidental deaths.

Table 8 shows time trends in death rates for principal causes of death for single years between 1970 and 1984 and decades since 1940. The death rate for the cardiovascular system reached a new State low of 365.4 in 1984. Death rate for cerebrovascular diseases have remained stable in the last three years. The death rate for the malignant neoplasms cause group has been increasing and reached 221.7 per 100,000 in 1984. Death attributable to accidents dropped by 2.1 percent to 27.9 per 100,000 in 1984.

Table 9 is presented in this series for the second year. It offers a comparison of New Jersey's overall death rate and death rates for principal cause groups with the United States rate age-adjusted to the estimated population in New Jersey for 1984. For example, if the population age-structure in the United States had been the same as New Jersey's age-structure the death rate for the United States in 1984 would have been 906.6 per 100,000 rather than 86.7 per 100,000. The difference between 906.6 and 866.7 can be attributed to the age-structure differences between the two populations, rather than the age-specific death rates. As can be seen, New Jersey's crude death rate of 917.4 per 100,000 is still higher than the United States age-adjusted rate of 906.6 meaning that age-specific death rates are higher in New Jersey's population than nationally. Age-structure accounts for the least difference between United States actual and adjusted-rates for accidents; pneumonia and influenza; septicemia; atherosclerosis; nephritis, nephrotic syndrome and nephrosis; suicide and homicide. New Jersey's cause specific death rates are lower than that for the nation for cerebrovascular diseases; accidents; atherosclerosis; suicide; and homicide. For two major cause groups - diseases of heart and malignant neoplasms - New Jersey's death rates are higher than that for the nation, even after controlling for age differences.

1984	1,090	10.8	744	7.4	1,062	10.5	1,806	17.7	11	1.1

NOTE:

- 1) Rates are expressed as per 1,000 live births.
- 2) Rates represent neonatal deaths plus fetal deaths per 1,000 live births plus fetal deaths.
- 3) Rates per 10,000 live births.

1984 NATALITY REPORT

INTRODUCTION

This annual Natality statistics report is part of an extended series of publications of similar format on deaths, marriages, abortions, morbidity and population. It is hoped that the user will find the format informative and easy to reference.

Statistics provided herewith are summarized from reported Birth Certificate items filed with the New Jersey State Registrar. The New Jersey vital statistics legislation requires that within five days of birth, the attending physician, midwife, or person acting as midwife, file a Certificate of Birth with the Local Registrar for submission to the State Registrar. Births to New Jersey residents that occurred during the calendar year in other states are recorded in the state of occurrence. This information is, however, forwarded to the New Jersey State Registrar and records are maintained on all New Jersey residents out-of-state births. To maintain confidentiality, individual identifiers are removed prior to tabulation of data for statistical purposes.

STATISTICAL OVERVIEW

Number of Births

Over the years, New Jersey's birthrate trend has closely paralleled that of the United States, though the state's rate has consistently been lower than that of the nation. In 1984, there were 100,950 resident births in New Jersey, the highest annual total since 1972. Births increased by 2.2 percent from the 1983 level of 98,746. Nationally, the number of births for 1984 reached the 3,697,000 level. This provisional level reported by the National Center for Health Statistics, indicates an increase of 2.3 percent for the same period. In 1984, 77,912 births were reported as white and 21,116 as nonwhite with 1,922 of unknown race. White births represented 77.2 of total births, while nonwhite births comprised 20.9 percent. White births indicated an increased 2.5 percent with the nonwhite births moving up 1.1 percent from 1983.

Of the total births in the State, 2.1% or 2,124 were twins with 55 (< 0.1%) being triplicates and others. By far, single births dominated live births in the State of New Jersey, representing 97.8% of all births for the year 1984.

The ratio of male to female births in New Jersey for 1984 was 1,042 male to every 1,000 female births. This male/female ratio was down slightly from the 1983 level of 1,051. Between 1983 and 1984, the male/female ratio for white live births remained declined slightly from 1,060 to 1,043 while nonwhites increased from 1,007 to 1,035 (2.8%).

Birthrate

During 1984, the birthrate in New Jersey rose 0.2 percent to 13.4 live births per 1,000 population. The birthrate is a measure of population increase. Camden County again recorded the highest birthrate (16.1) and Bergen County the lowest (10.3). Other counties with rates above the state rate of 13.3 were: Cumberland and Sussex both at (15.4), Atlantic (14.9), Hudson (14.8), Passaic (14.7), Gloucester (14.5), Essex (14.1), and Mercer (13.9).

Fertility Rate

The most significant demographic factors associated with rising birthrates are the increase in the number of women aged 15-44 years and an increase in the fertility rate. The measure of the rate of childbearing in New Jersey, increasing slightly from last year's level of 56.7 to a rate of 57.4 for 1984, and has fluctuated slightly since 1980, when the fertility rate was also 57.4. While the fertility rate now appears to have leveled off, one cannot lose sight of the fact that a downward trend has occurred in New Jersey; since the early 1970s, the overall fertility rate has dropped by nearly twenty-five percent.

Out-of-Wedlock-Births

The incidence of births out-of-wedlock in 1984 were recorded at approximately one of every 4.5. This 22.3 percent level of births for which illegitimate status was reported appears to have stabilized and has held this level for the last five years. For white women, the percentage of total births classified as illegitimate increased 0.3 percent, while for black women an increase of 1.4 percent was observed. The legitimacy ratio for births to white mothers was 86.9 in 1984 compared to 87.2 in 1983; for black mothers the legitimacy ratio was 35.8 in 1984 and 37.2 in 1983. The percentage levels of illegitimate births attributed to whites and nonwhites has remained about the same, 45.5% and 54.0% respectively, with the balance of 0.5% attributed to unknown.

Women 19 years and under gave birth to 34.5 percent of the children out of wedlock. Fully 75 percent of all births among women in this age group were illegitimate. In the 20-24 year maternal age group, the illegitimate rate increased by 1.7 percent over 1983 to a level of 33.3 percent. For mothers 25 years of age and older the illegitimate level was 9.7 percent. The 25-34 age group recorded 9.9 percent, an increase over 1983 of 0.6 percent.

NEWBORN HEALTH

Birthweight

The median weight group for newborns in New Jersey ranges between 6 lbs. 10 ozs. and 7 lbs. 11 ozs. Of total newborns during 1984, 36.3 percent were between 6 lbs. 10 oz. and 7 lbs. 11 oz. Almost two-thirds, 64.8 percent of the newborns weighed between 6 lbs. 10 ozs. and 8 lbs 13 ozs. The median weight group for newborns has remained the same and not changed during the last decade. The percentage of newborns, however, in the median weight group has declined slightly.

Premature, or low birthweight is defined as newborns weighing 5 lbs. 8 ozs. (2,500 grams) or less. Of all New Jersey resident births for which weight was reported in 1984, 6.9 percent were recorded as low birthweight babies. White births weighing less than 5 lbs. 8 ozs. number 4,391, 5.6 percent of all white births, while nonwhite immature births numbered 2,522, or 11.9 percent of all nonwhite births.

Statistics indicate that births to young mothers under 20 years of age are more likely to be immature. A total of 1,146, or 11.1 percent, of births to teenage mothers in 1984 were immature. Among nonwhite teenage mothers, the percent of births underweight was higher than for white teenage mothers. Underweight births to nonwhite teenage mothers represented 13.8 percent or 660 cases compared to 8.8 percent or 485 cases for births to white teenage mothers.

Previous Pregnancy Terminations

The number of previous pregnancy terminations a woman has had affects the incidence of low birthweight outcomes for subsequent pregnancies. The incidence of low birthweight births to women with no previous pregnancy terminations was 6.6 percent. The percentage of births immature increased, however, with the number of previous terminations. In 1984, the level reached to a high of 15.7 percent of births for women with more than three previous terminations.

Prenatal Care

There is a positive relationship between birthweight and prenatal care. Low birthweight infants are born less frequently to women who begin prenatal care in the first trimester of pregnancy. The rate among this group was 6.3 percent, a decrease over the 7.4 percent observed in 1983. The percentage of immature births among mothers starting care during the second trimester of pregnancy was 8.6 percent up from 5.9 percent in 1983. Among those beginning care in the third trimester, the ratio was 8.9 percent compared to 7.0 percent last year. Those receiving no prenatal care gave birth to low birthweight infants in 29.0 percent of the cases.

Apgar Score

The APGAR Score is a composite measure used to evaluate the newborn infant's general condition. APGAR Scores are given to newborns at one and five minutes after birth. Heart rate, respiratory effort, color, muscle tone, and reflexes are checked and evaluated. Each factor receives a score of 0, 1, or 2 and the sum of the five values is the overall score. A score of 10 is optimum. Newborns with scores less than 7 are considered distressed and are observed more closely for physical problems during the first days of life. There is a significant relationship between APGAR Score and birthweight, neonatal mortality, and neurological morbidity.

Twenty-nine percent of all newborns in 1984 received five-minute APGAR Scores of 10. Of total births, 93.9 percent were in the 7-10 APGAR Score range. Low APGAR Scores for newborns of nonwhite mothers were a more frequent occurrence than for newborns of white mothers. Among nonwhite births, 2.4 percent had scores less than 7. Only 1.1 percent of white births were in this low score range. When controlled for age of mother, low APGAR Score births were at the highest rate for the 19 or less group followed by teenage mothers and for mothers aged 45 and over. Among births to mothers aged 19 years and under, 1.9 percent had low APGAR Scores, low APGAR scores represented 3.6 percent of births to mothers under age 15, and 3.9 percent of births to women over 45 years of age. The percentage of newborns with low scores was 1.3 percent for mothers aged 20-44.

Low APGAR Score births occurred less frequently to mothers who received prenatal care. Of births among women receiving prenatal care, 1.3 percent were in the 0 to 6 score range. Among mothers receiving no prenatal care, 6.4 percent of births were low-score.

MATERNAL CHARACTERISTICS

Age

The median age group for mothers in 1984 was 25-29 years. Fully one third (34.1%) of all births were to women in this age group. Births to teenage mothers, 19 years and younger, accounted for 10.2 percent of the total, slightly lower than the proportion (of 11.0 percent) in 1983. Teenage deliveries were highest as a percentage of total births in Cumberland (21.4), Camden (19.0), Essex (17.3), Hudson (16.4), and Atlantic (15.7) counties. Bergen had the least (3.3%) proportion of births to teenage mothers, followed by Hunterdon (3.2%) and Burlington (3.3%). Women 35 years of age and older gave birth to 8.0 percent of the newborns. This represented an increase (from the 7.5 percent) of approximately 6.7 percent over 1983.

Race

Of total births, 77,912 (77.2%) were reported as occurring to white mothers and 21,116 (20.9%) to nonwhite mothers. This was approximately the same proportions as in the previous year. Since 1970 the proportion of total births that were nonwhite has increased slightly, about two to three percent, while a comparable decrease has occurred for the proportion of total births that were white. Births of unknown or unrecorded race numbered 1,922 (1.9%).

Prenatal Care History

There were 1,047,341 visits for prenatal care. This level of approximately 10.4 visits per patient, rose slightly and steadily from the 9.9 visits per patient in 1980. For women giving birth in 1984, 79.8 percent began prenatal care in the first trimester of their pregnancies and only 3.0 percent failed to receive care before the third trimester. Approximately 0.8 percent did not receive any prenatal care.

More white mothers began prenatal care in the first trimester than nonwhite mothers and fewer white mothers completed their pregnancies without any prenatal care. Of white mothers, 84.6 percent sought first trimester care. This was an increase of one percent over the 83.8 level for 1983, while nonwhite mothers showed a level of 68.6 percent receiving prenatal care during first trimester up from 65.6 percent in 1983. Nonwhite mothers were almost three times more likely not to receive any prenatal care than white mothers (1.6 percent compared to 0.6 percent). Prenatal care for all age-race groups was lowest for nonwhite teenagers with approximately one-half (53.2%) receiving first trimester care an improvement over the 48.8 percent in 1983 and 2.1 percent not receiving any prenatal care (compared to 3.1 percent in 1983).

First trimester care was lowest for teenage mothers. Approximately one half of the childbearing women in this age group, 5,604 (or 54.4%), received prenatal care from the first trimester of pregnancy. Of the 10,294 teenage mothers, 2.1 percent did not receive any prenatal care and 8.5 percent did not begin prenatal care until the third trimester of pregnancy. This represents a decrease (by 16.5%) of receipt of adequate prenatal care in this age group compared to last year. Data also indicates that attention to prenatal care increases with maternal age. First trimester care was received by 73.7 percent of the women aged 20-24 and 86.1 percent of the women 25 years of age and older.

Educational Trends

Educational level was reported on 94.5 percent of all birth certificates. Data show that over four-fifths, 82.3 percent of mothers were high school graduates and 22.5 percent were college graduates (up from 1983 when the percents were 76.4 and 20.2 respectively). There is an inverse relationship between family size and educational attainment of the mother. Among those who completed high school without further education, 43.9 percent had no previous live births while 7.4 percent had more than 2, and 2.5 percent had more than three. For mothers with some college, and mothers who graduated college, the number with three or more previous live births was lower (1.5% compared to 5.1% in 1982). For those with some college, (13.8%) had two previous live births, 4.4 percent had three, and 2.1 percent had more than three. Mothers who had not earned a high school diploma had the largest number of previous live births. Mothers in this group gave birth to 16.7 percent of all newborns, but comprised 28.0 percent of mothers with three previous live births and over one-third (39.7%) of those with more than three previous live births.

Attendant at Birth

A physician was in attendance at 97.3 percent of all resident births, while midwives attended 2.5 percent of all resident births. Data indicates a steady rise in midwife attendance, up over 1980 by 35.2 percent. Births to white mothers assisted by midwives increased substantially (by 14.7%) over the last year compared to the increase of 3.1 percent among nonwhite mothers assisted by midwives. Midwives attended 1,621 white births, 310 black births, and 38 births to other races.

1984 MORTALITY

INTRODUCTION

All mortality statistics provided are data summarized from Death Certificate items filed with the New Jersey Registrar. A death certificate is required to be filed by the proper authority for any death occurring within that state by New Jersey Vital Statistics legislation. Deaths to New Jersey residents occurring in other states during the calendar year are covered in this report and are recorded in the state of occurrence. These records are forwarded to the New Jersey State Vital Statistics Registrar as part of a National Data Exchange program between states.

All death data are maintained on computer tapes and are updated monthly. Monthly death tabulations are maintained by the Department of Health for surveillance and reporting purposes. To maintain confidentiality, all individual identifiers are removed prior to tabulation of any data item for statistical purposes.

The New Jersey Department of Health participates in the National Center for Health Statistics, Cooperative Health Program's death reporting and in the national death index.

STATISTICAL OVERVIEW

Number of Deaths

With the population of the State increasing by twenty-three percent over the last twenty-four years, as could be expected, the number of resident deaths has likewise increased. The increase, however, was not in a direct proportion and has occurred at a much slower pace. The mortality rate indicates that deaths per 1,000 population were lower in 1984, registering only a 16.2% gain over the 1960 level of 59,330. Total resident deaths during 1984 were recorded at a level of 68,944, this is an increase of 318 over 1983. There were 30,922 white male deaths, 30,029 white female deaths, 4,373 nonwhite male deaths, and 3,574 nonwhite female deaths.

Mortality Rate

The mortality rate for the State was 9.2 per 1,000 population, both in 1983 and 1984. Compared to the Nation, the New Jersey rate was slightly higher with the national mortality rate for 1984 at 8.7 per 1,000 population.

Distribution across the 21 counties varied from a high of 13.1 per 1,000 population in Ocean County to 6.7 per 1,000 population in both Hunterdon and Sussex Counties. A ranking by mortality indicates that the following counties were higher than the State average: Cape May (12.4), Atlantic (11.9), Hudson (10.4), Warren (10.0), Union (9.9), Essex (9.7), Monmouth (9.6), and Cumberland (9.4).

The New Jersey mortality rate for males (9.8) was higher than for females (8.6). This traditionally has been true over time. The white population rate of 9.7 was higher than the nonwhite rate of 6.6 for the year also based on the 1,000 deaths per population level. For population groups divided by both race and sex, the highest mortality rate occurred among white males (10.2), and the lowest rate among nonwhite females (5.6).

Age-Specific Rates

Comparisons of age-specific mortality rates by age groups for whites and nonwhites show higher mortality rates for nonwhites in age groups under 65. The difference between the two race groups became more pronounced with age: 1) for the 25-44 age group where the mortality rate for nonwhites (294.0 per 100,000 population) was 168.5 points higher than the rate for whites (125.5), 2) for the 45-64 age group the mortality rate per 100,000 population for nonwhites was 1,214.2 compared to 831.9 for whites (a difference of 382.3 points), and 3) for those persons aged 65 and above the rates were 4,885.7 for nonwhites and 5,227.1 for whites (a difference of 341.4 points in the opposite direction).

Male age-specific mortality rates were higher for all age groups than the corresponding rates for females. In the 15-24 year age group, the male rate of 108.7 per 100,000 population was nearly 2.6 times that of the female rate of 41.5 per 100,000 population. The mortality rate for males aged 25-44 (210.6 per 100,000 population) was over twice the rate for females (98.6 per 100,000 population). At ages 45 through 64 females had an age-specific death rate of 1,129.2 per 100,000 population compared to 643.6 per 100,000 population for males. The mortality rate for males aged 65 and above was 6,171.0 per 100,000 population compared to 4,571.8 per 100,000 population for females.

PRINCIPAL CAUSES OF DEATH

Leading Causes

The ten leading causes of death has remained virtually the same since 1968. Leading causes for 1984, in ranked order were: (1) diseases of the heart, (2) malignant neoplasms, (3) cerebrovascular diseases, (4) accidents, (5) pneumonia and influenza, (6) diabetes mellitus, (7) chronic liver disease and cirrhosis, (8) nephritis and nephrosis, (9) atherosclerosis, and (10) septicemia.

Deaths caused by diseases of the heart remained approximately at the same level as 1983 with the mortality rate dropping by 11.1 points to a 1984 level of 365.4 per 100,000 population. Malignant neoplasms increased slightly over the 1983 level, rising by 0.4% to a rate of 221.8 per 100,000 population in 1984. Combined diseases of the heart and malignant neoplasms, the two top causes of death, continued to account for almost two-thirds of all deaths in the State. Deaths attributable to malignancies, pneumonia and influenza, septicemia, diabetes mellitus, and nephritis and nephrosis all increased in numbers of deaths, while numbers of accidental deaths decreased as did number of deaths attributable to cardiovascular diseases, cerebrovascular diseases and chronic liver disease and cirrhosis.

Age Groups

Age group data show that accidents were the leading causes of death for the population ages 1-14, with malignant neoplasms second. For those aged 15-24, accidents were also recorded as the leading cause, with homicide and suicide tied for second. For age group 25-44, malignant neoplasms was the first leading cause, with accidents recorded as the second, followed closely by diseases of the heart, with suicide, chronic liver diseases and cirrhosis and homicide 5 and 6 respectively. For the age group 45-64 malignant neoplasms is the first ranking cause of death followed by heart diseases. For deaths to persons aged 65 years and over, disease of the heart was first, malignant neoplasms second, cerebrovascular third, and pneumonia/influenza fourth.

Diseases of the Heart

Diseases of the heart dropped from 28,104 deaths in 1983 to 27,460 in 1984. The slight drop in the total was reflected in a rate decrease from 376.5 to 365.4 deaths per 100,000 population. There were 12,725 deaths per white males in 1984, a slight drop from the 1983 level of 13,067. The white female total also declined from 12,655 in 1983 to 12,484 deaths in 1984. Deaths due to this disease among nonwhite males also showed a decline, moving from 1,243 to 1,120 in 1984. Nonwhite female deaths decreased by 10, from 1,131 to 1,121 deaths. Diseases of the heart remained the leading cause of death for all races, sixty-five and over, and for all males forty-five and older.

* Suicides are the 17th ranking cause of death among those persons aged 65 and above with 112 deaths from suicide in that age group.
 ** Excludes persons <1 year of age and persons of unknown age.
 *** Rankings 11 and 12 not shown for young age groups because of small number of cases in categories.
 **** Deaths from all other causes.

***** Deaths from all other causes.

Malignant Neoplasms

Malignant Neoplasms were the second leading cause of death in 1984, irrespective of race or sex. The crude mortality rates attributable to malignant neoplasms reported in 1984 as 221.8, in 1983, 220.8, in 1982, 217.3, in 1981, 213.7, and in 1980 at 210.5. Cancer was the second leading cause of death among white males over 44 years of age, and the third leading cause of death for white males aged 15-44. Among white females, cancer was the leading cause of death of women aged 25-64, and the second leading cause of death of those aged 15-24, and those aged 65 and older. Cancer resulted in the second highest death toll among men and women aged 45 and older, and was the leading cause of female mortality in the aged group 25-44. There were 1.1 percent more deaths attributable to malignant neoplasms in 1984 than in 1983.

Cerebrovascular Disease

Although cerebrovascular disease remained the third leading cause of death among New Jersey residents, the number of deaths has dropped for the fourth consecutive year. The overall trend since 1970 has been downward. Fully 84.0% of cerebrovascular disease deaths involved persons 65 and over. The mortality rates continued to remain higher in the white population, and among females compared to males.

Accidental Deaths

The number of accidental deaths dropped from 2,544 in 1981 to 2,373 in 1982 and 2,127 in 1983 to 2,099 in 1984. The accidental death rate correspondingly decreased from 34.4 to 27.9 deaths per 100,000, as a result of a both rise in total population and the decline in accidental deaths. More deaths were attributed to accidents than to any other cause of death among nonwhite males aged 25-44, and the second leading cause of death among white males and white females in this age group.

Influenza and Pneumonia

In 1984 there were 1,959 deaths in this disease category compared to 1,692 in 1983. The result was an increase in mortality from 21.8 in 1981, 20.1 in 1982, and 22.7 in 1983 to 26.1 deaths per 100,000 population in 1984. Influenza and pneumonia was the fourth leading cause of death among the elderly (aged 65+), accounting for 1,629 (or 83.2%) of the 1,959 total influenza and pneumonia deaths reported in 1984.

Suicide

There were 650 resident suicides in 1984, up from both 1983 in which there were 572 resident suicides and 1982 in which 605 resident suicides were recorded. The mortality rate rose to a level of 8.6 per 100,000 over 7.7 in the previous year. Deaths resulting from suicide were most frequent among the white male population, indicating a level of 437. There were 2 white male deaths between the ages of 5 and 14, 82 white male deaths between the ages of 15 and 24, 174 between the ages 25-44, 106 between the ages of 45 and 64, and 73 aged 65+. Among the nonwhite male population there were 52 deaths; these were recorded for men 15-24 (16), those aged 25-44 (21), and among those 45 years of age and over (14). By contrast, the highest age-specific deaths for white females were reported for those aged 25 to 44 and 45-64 (41 and 54 suicides for each of these two age groups respectively during 1984). Only 13 suicides were reported among nonwhite women.

Homicide

Homicide remains a major problem in New Jersey, with 435 unnecessary deaths occurring in 1984. In 1983 there were 447 homicides reported, in 1982 there were 548 reported homicides, in 1981 there were 558 homicides reported, and 530 occurred in 1980. Total homicides and rates per 100,000 population for the three years 1980 through 1982 were considerably higher than for any previous reported year within the State; the decline observed in the homicide rate between 1982 and 1983 was 18.9 percent. The homicide rate for 1984 was 5.8 per 100,000 population. The larger majority of homicides for white males were for the age group 15 to 64, with the highest level within the 25-44 ages. For black males the majority were within the range from 15 to 44. The highest percentage was also in the 25-44 group (69 cases or 43.4 percent). Nonwhite males recorded the highest homicide rate at 28.8 per 100,000 population which was fully six times higher than that for white males (homicide rate of 4.8 per 100,000 population). White females recorded the lowest rate at 2.4 per 100,000 population, while nonwhite females were at 7.2 per 100,000 population.

NOTE: *Total includes 2 males and 1 female of unknown race.

Other Selected Causes of Deaths

Diabetes mellitus accounted for 1,384 deaths in 1981, 1,248 deaths in 1982, 1,411 deaths in 1983 and 1,415 deaths in 1984. The 1983 death rate attributable to diabetes was 18.9 per 100,000 population compared to 18.8 per 100,000 population in 1984.

Chronic liver and cirrhosis diseases accounted for 1,032 deaths in 1984, compared with 1,132 deaths in 1983, 1,055 deaths in 1982 and 1,131 deaths in 1981. The death rate attributable to chronic liver disease and cirrhosis fluctuated as follows between 1981 and 1984: 15.4, 14.2, 15.2 and 13.7 per 100,000 population.

Other diseases of the arteries, arterioles and capillaries produced 725 deaths in 1984 compared with 689 deaths in 1983 and 728 deaths in 1982. The mortality rate for chronic liver disease and cirrhosis declined was 9.6 deaths per 100,000 population in 1984 (and 9.2 deaths per 100,000 population in 1983). Deaths from atherosclerosis numbered 765 yielding a rate of 10.1 per 100,000 population.

Bronchitis, asthma and emphysema deaths rose from 498 in 1983 to 567 in 1984. The corresponding death rates for these two years were 6.7 and 7.5 per 100,000 population.

INFANT, FETAL AND MATERNAL DEATHS

Infant Deaths

Infant mortality refers to deaths of persons under one year of age and is measured directly to the number of live births recorded during the same year. In 1984 the number of infant deaths was 1,090 compared to 1,115 in 1983 and 1,153 in 1982. The infant mortality rate decreased and recorded at 10.8 per 1,000 live births in 1984 compared to levels of 11.3 per 1,000 live births in 1983, and 11.7 per 1,000 live births in 1982. The 1984 infant mortality rate for the U.S. was 10.6 per 1,000 live births. Overall, infant deaths have been on a downward trend since the Department of Health started to collect and maintain statistical records in 1879, and 1984 was no exception to this trend.

There were 705 white and 376 nonwhite infant deaths during 1984 and 9 for whom race was unknown. The infant mortality rate for whites was 9.0 per 1,000 live births, a decrease from 9.3 per 1,000 live births in 1983. Among nonwhites the infant mortality rate also decreased, dropping from 1983 19.2 per 1,000 live births, to 17.8 infant deaths per 1,000 live births during 1984.

Infant deaths due to Respiratory Distress Syndrome increased by 0.68 over those reported in 1983; the numbers increased by one case to 149 in 1984. Sudden death, causes unknown (SID's) and disorders relating to short gestation and unspecified low birthweight were the only two causes within the top ten to show a decrease. Sudden death, cause unknown (SID's), the second ranking cause of infant deaths in 1984, decreased by 4 cases. It should be noted that most deaths attributable to SID's (91.0%) occurred after the neonatal period.

PRINCIPAL CAUSES OF INFANT MORTALITY 1983-1984

CAUSE DESCRIPTION (ICD-9 CODE)	1984		1983		Percent Change
	Rank	Number	Rank	Number	
Respiratory Distress Syndrome (769)	1	149	1	148	+0.68
Sudden Death, Cause Unknown (SID's) (798)	2	111	3	115	-3.48
Other Respiratory Conditions of Fetus and Newborn (770)	3	92	4	85	+8.24
Other and Ill-defined Conditions Originating in Perinatal Period (779)	4	84	5	79	+6.33
Disorders relating to short gestation and unspecified low birthweight (765)	5	83	2	116	-28.45
Other Congenital Anomalies of Heart (746)	6	60	6	55	+9.09
Fatal and neonatal haemorrhage (772)	7	33	22	13	+153.85
Other and unspecified congenital anomalies (759)	8	32	7	37	13.51
Intrauterine hypoxia and birth asphyxia (768)	9	32	13	20	+60.00
Other congenital anomalies of circulatory system (747)	10	25	17	17	+47.06

NOTE: ICD-9 Code 779 includes 779.6, four terminations of pregnancy (fetus).

Neonatal Deaths

Statistically, it has been observed that most infant deaths occurred during the first month of life. These are referred to as Neonatal Deaths. In 1984, there were 744 neonatal deaths, a decrease of 11 neonatal deaths from the number reported in 1983. The 1984 neonatal mortality rate was 7.4, a decrease of 0.2 per 1,000 live births, from the 1983 level of 7.6. New Jersey's 1984 neonatal mortality rate of 7.4 per 1,000 live births is 7.3 percent above the national rate of 6.9 per 1,000 live births. In 1984, there were 508 white and 229 nonwhite neonatal deaths recorded with 7 of unknown race. The neonatal mortality rates for whites and nonwhites were 6.5 and 12.3, respectively in 1983 compared to 6.5 and 10.8, respectively in 1984. The rate for whites remained stable over these two years while the rate among nonwhite mothers decreased by 13.9 percent.

Fetal Deaths

A fetal death is defined as a death occurring prior to complete expulsion or extraction of a fetus from its mother as a product of conception. Other commonly used terms are stillbirth and spontaneous abortion. Fetal deaths occurring after the completion of twenty or more weeks of gestation are required by law to be reported to the State Registrar.

Although the reported number of fetal deaths and the corresponding fetal death rate has declined over the past twenty-five years, the last nine years have been somewhat erratic with no fixed course discernable. In 1958, there were 2,185 fetal deaths with a rate of 16.8 fetal deaths per 1,000 live births. In 1975, 941 fetal deaths were reported producing a rate of 10.3. In 1976 and 1977, 1,004 and 1,083 fetal deaths were recorded producing rates of 11.1 and 11.5, respectively. The figures for the years 1978 to 1981 trended downward until 1982 which increased to a level of 10.3 and registered at a level of 1,008 fetal deaths. In 1983 the level decreased to 839 or 8.5 per 1,000 births but in 1984 the number and rate again both rose to 1,062 fetal deaths for a rate of 10.5 per 1,000 live births.

The number of white fetal deaths decreased from 625 in 1982 to 491 in 1983 and rose to 654 in 1984, while nonwhite fetal deaths decreased from 353 to 323 from 1982 to 1983 and then rose to 374 in 1984. The fetal death rate for the white population declined by 21.7 percent from 8.3 in 1982 to 6.5 in 1983 and then rose to 8.4 per 1,000 live births in 1984. For the nonwhite population, the rate decreased by 8.8 percent from 17.0 in 1982 to 15.5 in 1983 and rose to 17.7 per 1,000 live births in 1984.

Perinatal Deaths

Perinatal mortality is a composite statistic used to measure the critical period in human development just prior to birth and shortly thereafter. Perinatal mortality, as presented herewith includes fetal deaths of 20 weeks or more gestation plus neonatal deaths (infant deaths under 28 days of age). During the last twenty-five years perinatal deaths have been reduced dramatically. The perinatal mortality rate in 1958 was 35.0 and has declined to 17.9 in 1984.

There were 1,806 perinatal deaths in 1984, an increase of 210 from 1983. The perinatal mortality rate increased from 16.1 to 17.9 deaths per 1,000 live births. The same condition observed with Fetal Deaths is also true in the case of Perinatal Deaths. The long-term trend shows a substantial drop over the last fifty years with minor fluctuations recorded for the short term. Perinatal rates for whites and nonwhites were recorded as 14.9 and 28.6 per 1,000 live births, respectively for 1984, an increase from the 1983 rates of 12.9 and 27.7 per 1,000 births, respectively.

Maternal Deaths

Maternal deaths have been reduced drastically since 1940 when they were observed at a level of 172 and with a rate of 29.0. The lowest number occurred in 1980 with only 5 and a rate of 0.5. During 1981 the number moved up to 7 and again increased slightly in 1982, with 11 deaths recorded while in 1983 the number again reached the low of 5 and in 1984 returned to the 1982 level of 11 deaths. The 1984 rate was 1.1 per 10,000 live births (same as in 1982) as compared to the 1983 rate of 0.5 per 10,000 live births and the 1981 rate of 0.7 per 10,000 live births.

1984 MARRIAGES AND DIVORCES

INTRODUCTION

Marriage statistics provided in this report were tabulated from items reported on Marriage Certificates filed with the New Jersey State Registrar for calendar year 1984. Divorce data have been provided by the New Jersey Superior Court, Chancery Division. Both Marriages and Divorces are recorded by place of occurrence or judgment. Therefore, statistics presented refer to the number of events occurring within New Jersey irrespective of place of residence of the participants. To maintain confidentiality, individual identifiers were removed prior to the tabulation of the data. Rates published in this report for both Marriages and Divorces are based on the 1984 New Jersey Annual Estimates of Population released by the New Jersey Department of Labor.

STATISTICAL OVERVIEW

Number of Marriages

The number of marriage certificates issued in New Jersey during 1984 increased for the seventh consecutive year. This is the highest level recorded since the start of marriage statistical reporting, and surpassed the 1946 high, the year following the end of World War II; the level that year reached 61,020. The number of marriages for 1984 were recorded at the level of 62,654, an increase of 856 from 1983. This numeric gain was not enough to increase the rate of marriages per 1,000 population which remained at a level of 8.3. This rate is the highest marriage rate per 1,000 population attained since 1951 (when the level was 8.9 per 1,000 population). A low in the number of marriages and rate per 1,000 population was reached in 1977 but has been progressively increasing. The overall gain from the 1977 level was 23.6%.

The greatest number of marriages occurred in Essex County (7,591) with the lowest level recorded for Salem (426). Seven of the state's counties accounted for almost 60 percent of the marriages during 1983. These all recorded 4,000 or more and in descending order are Essex (7,591), Bergen (6,917), Hudson (5,184), Monmouth (4,407), Union (4,277) and Passaic (4,126). The rate of marriages per 1,000 population has increased over the 1977 to 1984 seven-year period over one (1.4) percentage point. During 1984 Cape May County recorded the highest marriage rate (9.6 per 1,000 population), followed by Atlantic (9.5 per 1,000 population). Ocean and Salem Counties had the lowest rates (6.8 and 6.5 per 1,000 respectively).

Previous Marital Status

Data on marital status showed the proportion previously married for both men and women has remained stable over the past three years. The increase in first marriages between 1983 and 1982 were 0.3 percent for men with a slight decrease (of 0.1 percent) for women. Sixty-two percent of all marriages were between persons marrying for the first time and 73.9 percent of all marriages were for women marrying for the first time. Divorced men represented 24.8 percent with divorced women 22.8 percent.

Age

The average age at time of marriage (regardless of previous marital status) was 28.4 years for women and 31.0 years for men (rising for both sexes women by almost two years). In 1983 the mean ages were 26.7 years for women and 29.5 years for men.

The average age at time of first marriage was 27.1 years for men and 25.3 years for women. The number of women and men marrying before the age of 25 continues to decline. In 1984, 43.8 percent of women (27,470) married under age 25 compared to 46.3 percent of the women (28,597) in 1983, 48.6 percent (or 29,163 women) in 1982 and 51.2 percent (or 29,699 women) in 1981. The same pattern also applied to men marrying before the age of 25. Here a level of 29.4 percent (18,417) was observed in 1984; down two percent (or 787 instances) from the number in 1983 (19,204). In 1981 comparable figures were 35.8 percent or 20,793 males marrying before age 25. Teenage brides, likewise, continued their downward trend to a level of 4,997 compared to 5,485 and 5,862 in 1983 and 1982. Teenage brides comprised 8.0 percent of all brides in 1984 compared to 8.9 percent, 9.9 percent and 11.1 percent in 1983 through 1981, respectively.

DISSOLUTION OF MARRIAGE

Total Divorces

For every two marriages that took place during 1984, one was dissolved. There were 28,470 divorces and annulments during the 1984 calendar year. This was a total of 547 more than for the 1982-1983 court year.* The 1981-82 court year was the highest total on record with 30,322 divorces. The divorce rate decreased while the marriage rate increased over last year. The marriage dissolution rate, the number of dissolutions per 1,000 population, reached 4.1, an all-time high in 1982, and in 1983 and 1984 returned to the same rate experienced in 1981 (3.8 per 1,000 population). The occurrence of divorces almost paralleled that of marriages at the county level. While the order was slightly different, the top ranking seven counties were the same. These counties, Bergen, Essex, Middlesex, Monmouth, Hudson, Union and Camden counties accounted for over 50 percent of the dissolutions that took place.

*Court Year: September 1, 1982 - August 31, 1983, divorce records tabulated based on calendar year from 1984 forward.

MUNICIPALITY VITAL STATISTICS SUMMARY

INTRODUCTION

Available vital statistics for Births, Deaths, and Marriages show various levels between New Jersey Counties and Municipalities. Annually, the New Jersey Department of Health has produced a County table with individual Municipality summaries of Marriages, Births and Deaths (infant, fetal, neonatal). The table has also carried the latest Population totals for each Municipality, released by the New Jersey Department of Labor, Office of Demographic and Economic Analysis.

The special County-Municipality tables were originally produced to provide Vital Statistics information to local Health Officers and various programs within the Department of Health. Increased requests have been received by researchers and the public to publish this information. Thus, this section presents the seven above-mentioned items, giving a table summarizing all county data and individual tables for each of the 21 counties and 567 municipalities in New Jersey. Crude birth or mortality rates have not been calculated at the municipality level, but are presented elsewhere in this report for the State and each of the 21 counties.

**ESTIMATED POPULATION, MARRIAGES, BIRTHS, DEATHS, INFANT DEATHS,
FETAL DEATHS AND NEONATAL DEATHS BY COUNTIES: 1984**
(Marriage data by place of occurrence, all other by place of residence)

FERTILITY PATTERNS IN THE NATION AND NEW JERSEY

1984

THE AMERICAN WOMEN

The average number of lifetime births expected by young wives in the U.S. who were 18 to 24 years old in 1983 was 2,225 births per 1,000 wives and has remained essentially unchanged since 1975. From a longer time perspective, however, the average number of lifetime births expected by wives 18 to 24 years old has declined from 2.9 births per married women in 1967 to 2.1 births in 1980 and is currently at a level of 2.2 births per married women (in 1983).

It is not certain whether the recent stability in birth expectations is transitional and will lead to further decline in fertility or whether it indicates a new demographic trend in the United States. If the latter proved to be the case, the pattern of American fertility in future years will follow that of many Western European nations and Japan, namely, small fluctuations in fertility around the level needed for the natural replacement of the population (approximately 2.1 children per women).

From marriage data it is known that in recent years there has been an increasing tendency for women to delay their first marriage and first birth to older ages. Of those women who first married between 1965 and 1969, 69 percent married by age 21; this proportion declined to 60 percent for women who first married during the 1976-80 period. The median age at first marriage has risen for both sexes since 1965; in 1981 the median ages were 22.0 years for females and 23.9 years for males. In addition, 56 percent of all first births between 1965 and 1969 occurred to women 21 years older and under; this percentage dropped to 47 percent for women having their first birth between 1976 and 1980.

Further, the longer a woman postpones childbearing after her first marriage, the less likely she is to have any children at all. In 1982 20.4 percent of women ever married, between the ages 15 and 44, were childless compared to 18.8 percent in 1980. Most importantly, 57.4 percent of women ever married, ages 15-19, were childless in 1982 compared to 46.6 percent and 52.8 percent in 1980 and 1981, respectively.

These data show that the fertility rate for nonwhite women during the 1977-81 period was much higher than recorded for white women; about 86 births per 1,000 nonwhite women 15 to 44 years old compared with an average of only 64 births to 1,000 white women in 1981.

THE NEW JERSEY WOMEN

Since 1960 fertility patterns of New Jersey women of childbearing age have shown a double reversal of trend. The decade of the forties was the end of a long period of declining fertility. The fifties showed the fertility rates increasing steadily, reaching their highest levels. In 1960 we had 9.8% fewer women aged 20-24, for instance, than in 1950. However, the State had approximately 12,328 more births in this age group, a 45% increase in births.

For women 20 to 24 years of age, the changing fertility rates over the past 30 years has been dramatic. From the 1950 level of 151.1 the rate rose to reach a level of 240.6 by 1960. This represents an increase of nearly 90 per thousand. During the decade of the sixties the decline was as equally dramatic, dropping from the 240.6 per thousand level to 154.8 in 1970. This placed the rate back almost to the 1950 level. The 1970 to 1980 period showed a low of 67.0 per thousand for this age group of 20 to 24. The 1984 rate is 79.8 per thousand - down from 87.0 per thousand in 1980.

A review of all age groups shows that the change since 1960 is a reversal to lower fertility rates. The decline in fertility rates by individual age groups has ranged in 1960 from a rate of 34.8 for women 35 years and older to 58.3 for those under twenty. In 1980, the range was from 12.5 (35 years +) to 35.2 for those under 20. The rates for all ages are now below the 1970 rates, but in New Jersey the fertility rates for 1984 were up slightly over 1983 for women ages 25 and above.

New Jersey's trend in fertility rates compares with national statistics, with U.S. fertility rates of 65.4 per 1,000 women and 66.0 per 1,000 women in 1983 and 1984, respectively and fertility rates in New Jersey at 56.7 and 57.4 per 1,000 women for the same two years. New Jersey's lower fertility rates are attributable, in part, to the age structure of the female population.

The age-specific fertility rates for younger (ages 15 to 24) women in New Jersey have been declining over the period 1980 to 1983, while over that same time period the age-specific fertility rates for women aged 25 and over have been increasing. This trend has important positive socio-economic implications.

With the use of age-specific fertility rates it is possible to calculate "total fertility rate" (TFR) which summarizes the changes in fertility. The rate is computed by summing the age-specific rates for all childbearing ages and multiplying by the number of years in each age group used. In this case the age interval is five (5) representing five ages in each group. It can be interpreted as the number of children that would be born to a cohort of one-thousand women if, at all childbearing ages, they bore children at the age-specific rates observed in the reference year. Since, at present death rates and with a sex ratio at birth of 106 males per 100 females, it requires a little over 2,100 births per thousand females to replace themselves in the next generation, the total fertility rate gives us a measure of the fertility growth factor in the population. Thus, as the TFR

exceeds 2,100 the next generation will have a larger childbearing population than the present and when the TFR declines below 2,100 for any extended period, the next childbearing generation will be smaller.

In 1950, the TFR for New Jersey was very close to replacement. By 1960 it had risen by 38.4 to 3,446 and by 1970 the drop of 30% brought the level to 2,408. Had that TFR continued, the childbearing population would have doubled in a single generation. The decline of the TFR during the sixties was greater than the rise in the fifties, and the single year decline between 1970/71 and 1971/72 shows the most rapid decline of any year for which we have detailed data. The TFR appears to have "bottomed out" in the late 1970's, as the number of births did earlier in the 1970's. In 1980, the 1,604 value was still 30.9% below replacement fertility level. By 1984, however the rate was once again on the rise to 1,635.

Further, the decline during the 1970-1978 appears to be in part a temporary phenomenon. It is probable that some of the observed decline during the same span represents both postponement of marriages and of births. Whether or not postponed births are ever realized depends on a number of factors associated with the economy, including employment opportunities for both men and women, cost of living, attitudes about family size, and availability of contraception and abortion. The increase in Marriages in the State (as reflected in the rising marriage rate since 1982), no doubt, will have a profound impact on births over the next few years.

INDUCED ABORTIONS 1984

INTRODUCTION

The Department collects data on induced abortions performed in all licensed abortion facilities in the State. Abortions performed in hospitals and licensed outpatient abortion facilities must be reported to the Department within 10 days after the close of the month the procedure was performed. Forms are provided by the Department and are processed monthly. A yearly summary report is compiled. The form is designed to provide data which can serve as a basic resource for health professional decisions relating to abortions, in planning abortion services and in providing family planning services. Data collected include information on age, marital status, municipality of residence, race, prior number of pregnancies and prior live births. Clinical information is limited to gestation period at termination and method of termination. Patients' names are never reported to the Department; therefore confidentiality is retained.

This report includes a narrative summary which presents related clinical information and demographic characteristics of the women represented in the 1984 data collection. Tables are included to illustrate these summary data. The statistics presented in this report are for induced abortions occurring only in licensed New Jersey health care facilities. Data can be obtained for residents obtaining abortions in other states from the National Center for Disease Control, Atlanta, Georgia.

OVERVIEW

Selected Characteristics

The number of induced abortions reported to be performed in New Jersey was 31,236 in 1984 compared to 24,722 in 1983 and 30,269 in 1982. The percent increase from 1983 to 1984 was 26.4; quite a contrast compared to the decline from 1982 to 1983 of 18.3 percent. In 1984, women who obtained an induced abortion in New Jersey were predominantly state residents (97.4%). Those who sought abortions within New Jersey from out-of-state had a significantly higher ratio of abortions to live births (449 per 1,000 live births) compared to 315 per 1,000 live births for New Jersey residents. The majority of women were Caucasian (51.1%) followed by 35.3 percent for Blacks. The average age among women receiving induced abortions in 1983 was 24.6 years compared to 24.4 years in 1984. Most of the women (75.5%) were unmarried, less than 25 years of age (60.1%) and childless (53.1%). The majority of abortions (83.5%) were first trimester procedures by sharp or suction curettage (99.4% of first trimester cases and 95.9% of all cases). A licensed out-patient abortion clinic, as in previous years, was the primary setting used and in 1984 accounted for nearly two-thirds (66.0%) of all abortions performed and 66.5 percent of the first trimester procedures.

Age

More than one-third (34.8%) of all the 1984 abortions were performed on women in the 20 to 24 age group. Nearly one-fourth (24.8%) of the women were between 15 to 19 and 20.8% were 25 to 29. The under 15 and over 44 age groups accounted for slightly less than 1.3% of the 31,236 reported abortions. Conversely, the induced abortion ratio for both extremes of the age spectrum were notably higher than the ratios for the middle ranges. There were 1,431 abortions per 1,000 live births for women in the "under 15" age category (up from 1,138 abortions per 1,000 live births for women under age 15 in 1983: a 25.7% increase) and 1,346 induced abortions for women over the age of 44. The two lowest abortion to live birth ratios were associated with the 30 to 34 age group (151) and the 25 to 29 year olds (194), showing an increase over respective ratios for 1983 (132 and 156). The 1984 abortion ratio for New Jersey women was 315 induced abortions per 1,000 live births, an increase of 23.0% from the ratio for 1983 (257), bringing the 1984 ratio in line with the 1982 ratio (of 316). (One abortion reported for every 3.2 live births).

The abortion ratio is defined as the number of women obtaining legal abortions divided by the number of women giving birth in the population in the same year with the same given demographic characteristics (such as residence, age, race, marital status, or number of previous live births) times 1,000. The purpose of this ratio is to try to locate where in the life cycle with respect to either age or previous number of live births for example, women are more likely to receive an induced abortion than at other points in the lifecycle.

Race

The women reported having induced abortions in 1984 were self-reported as white (51.1%), 47.7% as nonwhites and 1.2% as unknown. These percentages closely approximate those for previous years. There has been a gradual decline,

however, in percentages of whites with a gradual gain in relative numbers of nonwhites who have obtained induced abortions. In 1979, the percentages of white women equaled 64.4%; dropping to 60.4% in 1980, 58.9% in 1981, 54.2% in 1982 and 53.2% in 1983. Women who indicated race as black increased from 26.2% in 1980 to 35.3% for 1984.

The ratio of induced abortions to live births decreased between 1982 and 1983 for both whites and nonwhites and increased between 1983 and 1984. For white women, the ratio declined from 219 to 174 between 1982 and 1983, and then rose to 207 in 1984. The same ratio fluctuated for black females moving from 518 to 445 and then 592 induced abortions per 1,000 live births over the years 1982, 1983 and 1984.

Marital Status

Unmarried women represented 75.5 percent of the total induced abortions in 1984. The two age categories which accounted for slightly over one-half, were unmarried women aged 15-19 (23.6%) and unmarried women aged 20-24 (29.1%). Married women who received abortions exceeded those for unmarried women in all age groups after 29. There were 23.1 percent more married women than unmarried women who were over 29.

Prior Number of Live Births

Abortion data reported for 1984 indicated the majority (53.1%) of women had never given birth at the time of pregnancy termination. Just over one-fifth (22.0%) of the women indicated having one previous live birth, with 16.0 percent having two previous live births. Fewer than one in ten (8.7%) were listed with three or more.

The lowest induced abortions per 1,000 live birth ratio (211) was computed for women who had one previous live birth. Women with three previous live births had the highest ratio of abortions to live births (388 per 1,000) with women having no, two or four previous births very similar (377, 357 and 346 respectively).

Place of Residence

The majority of women (97.4%) who elected to have an abortion in New Jersey were in-state residents. Essex was the most frequent place of residence (25.6%) with the lowest (0.1%) recorded in Salem County. More than one-half of 1984 abortions were obtained by women who indicated Essex (25.6%), Hudson (11.9%), Bergen (9.2%), or Passaic (8.2%) as counties of residence. Correspondingly these areas rank as the four most heavily populated counties in New Jersey. Middlesex County experienced the greatest increase in number of abortions performed (an increase of 1,139 cases or 128.7%). Somerset County experienced the greatest percent increase (131.5% or 239 cases).

For the 1984 reporting period, women originated from twenty one states and several foreign countries were represented. The border states of Pennsylvania and New York were most frequently recorded by out-of-state women. Pennsylvania accounted for 44.0 percent (350) of all nonresident abortions while New York represented 48.6 percent (386) of the total.

Type of Procedure

The types of procedure most frequently reported were suction (65.6%) or sharp curettage (30.2%). These two procedures accounted for nearly all (99.4%) reported first trimester abortions and 98.0 percent of the procedures performed during the 13th to 15th week of pregnancy. Saline instillations represented 3.3 percent of all reported induced abortion procedures. The drug Prostaglandin was administered in 1.4 percent of the late second trimester abortions down from 2.0% in 1983, 3.6% in 1982 and 8.0% in 1981. Suction curettage was used in 26.7 percent of the cases beyond 15 weeks compared to 13.9 percent in 1983 and 1.3 percent in 1982. Ratios for saline instillations (32.6%) and sharp/suction curettage (65.7%) performed during the 16th to 20th week of gestation are not as close as they were in 1983 (42.3% and 55.1% respectively) representing a takeover of sharp/suction curettage which was 44.6% of this category in 1982 with saline 51.0% in 1982. It should be noted the categorization of 16 to 20 week gestation includes two relatively distinct stages of pregnancy requiring different abortion procedures.

Weeks of Gestation

Of the 31,236 reported 1984 induced abortions, 83.5 percent were completed during the first trimester pregnancy. This represents a decrease of 1.4 percent from 1983. The proportion of abortions performed during the 13th to 20th weeks increased slightly over the 14.2 for 1983 to 16.5 percent in 1984. Four hundred twenty-seven women (1.4%) underwent a late second trimester abortion (over 20 weeks) relative to 0.8 percent reported for 1983.

More than one-third (35.1%) of all first trimester abortions were performed on women in the 20 to 24 age group. Percentages were nearly equal for the 15-19 (22.4%) and women 25-29 groups (21.9%). Women who terminated pregnancy in the 13th to 20th week of gestation were most frequently between 15-19 (37.7%), and one-third (33.7%) were in the 20-24 range. Of the women estimated to be more than 20 weeks pregnant at the time of the reported abortion, 36.3 percent were in the group 15-19 and 30.4 percent 20-24. The same figures for 1983 were 39.8 percent and 29.1, respectively. There were three women between the ages of 40 and 44 represented in the over 20 weeks gestation classification, and only 12.7% were between the ages of 30 and 44 years.

Type of Facility

The 1984 data on induced abortions were collected from hospitals and licensed outpatient abortion facilities. The percentage of abortions performed in hospitals has increased steadily from 1979 to 1981 and then stabilized throughout 1983, with a decline observed between 1983 and 1984. In 1979, 28.6 percent were performed in a hospital setting, 32.6 percent in 1980, 38.1 percent in 1981, 36.0 percent in 1982, 37.9 percent in 1983, and 34.0 percent in 1984. Outpatient facilities accounted for 66.0 percent of 31,236 reported abortions in 1984. Most (83.5%) of the 13 to 15 week pregnancy terminations were completed in a licensed outpatient facility, as well as 66.5 percent of all reported first trimester abortions. All (with the exception of one) pregnancy terminations performed after 20 weeks and 42.1 percent of those completed during the 16th to 20th week were reported by hospitals. In contrast in 1983, 51.7 percent of those abortions performed during the 16th to 20th week were performed in hospitals. Of all single women who had an abortion in 1984 two-thirds (68.3%) went to clinics. Married women were more likely to use an outpatient facility in 1984: 61.6% of married women had procedures in outpatient facilities compared to 58.0% in 1983.

Number of Previous Abortions

Information submitted indicated most women (57.0%) had never undergone a previously induced pregnancy termination. Approximately one-fourth (27.3%) of the women had obtained one prior abortion, and in 1984, for 15.3% two or more previous abortions were reported. A comparison with 1983 shows a similar likelihood to present for first abortion (57.0% first trimester in 1984 compared to 56.7 percent in 1983), indicating that recidivism is not increasing.

ABORTION REPORTING GUIDELINES

The Department of Health in cooperation with the State Board of Medical Examiners, the New Jersey Obstetrical and Gynecological Society, and the Medical Society of New Jersey have adopted the following guidelines (applicable to abortion data) which were made necessary by the United States Supreme Court's decision regarding abortion:

1. Only persons licensed as physicians are permitted to perform abortions.
2. First Trimester abortions (on or before 12th week of pregnancy) may be performed only by qualified physicians in their private offices (if the patients medical condition permits) or in licensed health care facilities (i.e., hospitals or out-patient abortion clinics).
3. Beyond the first 12 weeks and within a period of gestation not exceeding 16 menstrual weeks and/or 14 gestation weeks (size as determined by a physician) termination of pregnancy using the dilation and evaluation procedure can be performed either in a licensed hospital or out-patient abortion clinic; if any other method of abortion is utilized to terminate a pregnancy during this time it must be performed in a licensed hospital on an inpatient basis.
4. Termination of a pregnancy after the 16th menstrual or 14th gestation week will only be performed in a licensed hospital on an inpatient basis.
5. Third trimester abortions are allowed only to preserve the life or health of the mother, or where it has been determined late in pregnancy that there is a nonviable or deformed fetus incapable of extrauterine survival.

Morbidity

INTRODUCTION

Overview

In the past morbidity data released by the New Jersey Department of Health have always pertained to Reportable Diseases. These data were and are collected and compiled by various programs throughout the Department. For example, programs like Tuberculosis Services collect information on all cases occurring in New Jersey in their monitoring and surveillance activities. Incident data on syphilis and gonorrhea are collected by the Sexually Transmitted Disease Program, and other communicable diseases, as required by Law, are reported by the Communicable Diseases program under Epidemiology and Disease Control.

Beginning in 1976 the Department of Health developed and has maintained a uniform minimum data reporting system for hospitals known as the Medical Discharge Abstract Minimum Data Set. Facilities covered by the Department's "Standard Hospital Accounting and Rate Evaluation System" (SHARE) were required to supply patient specific information to conform to the NJ/DOH Discharge Abstract Minimum Data Set. The Department can now report on all principal and secondary diagnoses relating to each discharged patient.

This report contains three subject areas. The first section covers all major communicable diseases that are required by law to be reported to the New Jersey Department of Health. The second section on Hospitalization describes the data categories for a statewide summary of hospital discharge statistics for 1983, including a summary of the forty (40) principal causes of hospitalization for 1982/1983. All tables are presented in the third section.

Beginning with the 1985 Health Statistics report, a new section has been added to cover communicable diseases. Data for 1985 are reported in the new section, along with a summary of AIDS cases and deaths. Future Health Statistics reports will include separate reports for communicable diseases and hospitalizations, rather than one section titled "Morbidity."

REPORTABLE DISEASES

Statistical Overview

Morbidity data are collected and compiled for all reportable diseases in New Jersey. The Tuberculosis Program collects information on all tuberculosis cases occurring in New Jersey. Incidence data on syphilis and gonorrhea are collected by the Sexually Transmitted Disease Program. Information on other diseases which are required by law to be reported are collected by the Communicable Disease Program of the Division of Epidemiology and Disease Control. These diseases include amebiasis, aseptic meningitis, brucellosis, hepatitis, malaria, measles (rubeola), meningococcal infections, mumps, pertussis, rubella, salmonellosis, shigellosis, tetanus, trichinosis, tularemia, typhoid fever and typhus. Requests for details on specific information regarding any of these disease conditions should be addressed to the above mentioned programs.

Tuberculosis

In 1953 there were 4,189 diagnosed cases of tuberculosis or 79.9 cases per 100,000 population. By 1980, newly diagnosed cases had dropped to 980 or 13.3 per 100,000 population. The long term decline in the number of new cases ended in 1981 with a swing upward to 1,028 cases. Minor fluctuations have occurred since 1981 with a decrease to 884 cases in 1982 and increases to 891 in 1983 and 935 in 1984. Likewise, the rate per 100,000 population increased in 1981 to 13.9, then decreased in 1982 and 1983. In 1984 it rose to 12.4. The annual number of deaths attributed to tuberculosis has followed a somewhat similar pattern dropping from 693 deaths in 1953 to a low of 53 deaths in 1982. The number of deaths due to tuberculosis increased in 1983 to 56 and in 1984 to 70. The mortality rate per 100,000 population declined from 13.2 in 1953 to less than one death (0.9) per 100,000 for 1984.

In 1983 809 clinically active cases of tuberculosis existed in the New Jersey population. In 1984 clinically active cases were 790. From an active case rate of 10.9 per 100,000 in 1983, the rate dropped to 10.5 statewide in 1984. Tuberculosis morbidity rates were higher for the larger cities in New Jersey. In 1983 and 1984 the rates were: Newark 50.0 and 44.6, Atlantic City 29.6 and 43.6, Paterson 42.6 and 44.4, Jersey City 50.0 and 45.4, and Elizabeth 27.2 and 29.7.

Venereal Disease

During the last twenty years the number of syphilis cases among residents of New Jersey has decreased dramatically. In 1963 there were 5,613 reported cases of syphilis compared with 2,636 cases in 1972 and 1,930 cases in 1982. In 1983, however, the number rose to 2,088 - an increase of 8.2%. The large decrease between 1963 and 1972 was basically a reflection of improved methods of tabulation that resulted in the elimination of duplicate counting of cases. Between 1972 and 1982 the modified reporting system was employed and a decline of 26.8 percent was recorded. The 1984 total of 2,006 cases produced a rate of 26.9 per 100,000 cases compared to the 1972 rate of 36.0. Likewise the number of primary and secondary cases dropped from 942 to 678 between 1972 and 1984 with a corresponding drop in the morbidity rate from 12.9 to 9.0 cases per 100,000. The number of cases diagnosed as early latent syphilis decreased 5.9 percent during this period from 8.3 to 7.6 per 100,000. The 1984 total of 2,006 cases of syphilis included 678 primary and secondary cases and 572 early latent cases.

In contrast to the decline in the number of syphilis cases, the prevalence of gonorrhea soared between 1965 and 1984. The number of gonorrhea cases climbed from 3,938 cases in 1965 to 18,837 cases in 1977, a fivefold increase. The increase continued, and by 1981 a high of 22,998 cases were reported with the morbidity rate quintupling from 61.0 in 1963 to 309.9 cases per 100,000 population in 1981. Since 1981 the number of gonorrhea cases has decreased to 22,075 in 1983 and to 20,351 in 1984. Correspondingly, the rate declined to 270.8 in 1984. Gonorrhea cases reported in the military also have declined from 534 cases in 1977 to a low of 250 cases in 1984.

Hepatitis

The number of reported cases of infectious hepatitis (A) increased in 1984 to 656 from 546 cases in 1983. The corresponding rates were 8.7 per 100,000 in 1984 and 7.3 in 1983. Serum hepatitis (B) cases declined from 1,174 cases in 1983 to 1,052 cases. Approximately 62 percent fewer cases of unspecified hepatitis were reported in 1984 than in 1983. The incidence rate dropped from 5.1 in 1983 to 1.9 per 100,000 persons. Hepatitis incidence was higher for men than for women. In 1984 there were 11.1 cases of infectious hepatitis per 100,000 men compared with 6.5 cases for every 100,000 women. In 1984 the rate for serum hepatitis in men was 18.3 compared to a rate of 10.0 in women. A total of 82 cases of unspecified hepatitis were reported among men (2.3 per 100,000) compared with 60 female cases (1.5 per 100,000) in 1984. In general, the rate of hepatitis cases increases from birth to 29 years of age, then decreases for older age groups. The total case rate for both infectious and serum hepatitis was highest in the 20 to 24 age group in both 1983 and 1984. In 1984 both men and women aged 20 to 24 had the highest rates. In 1983 the highest rates for men occurred in the late twenties for both infectious and serum hepatitis. Please note that in 1983 a change in the reporting of hepatitis occurred. A new category, Type Non-A and Non-B, was added. Between 1983 and 1984 the rate of Type Non-A and Non-B remained the same at 1.4 cases per 100,000 population.

Other Notifiable Diseases

As required by law the occurrence of contagious diseases must be reported to the State Health Department. These diseases include mumps, measles (rubeola), rubella (German measles), typhoid fever, malaria, aseptic meningitis, as well as a host of other contagious diseases. In both 1983 and 1984, the incidence of most of these diseases declined.

The number of cases of measles (rubeola) dropped from 27 in 1983 to 7 in 1984. The number of cases of measles, however, fluctuates enormously from year to year. In 1976, for example, 690 cases were observed, while in 1974 there were 5,693 cases. A decade ago the number of cases of rubella (German measles) rose by 19.7 percent with 1,775 cases in 1977 compared to 1,483 in 1976. In 1984 only 23 cases were reported compared to 3 cases in 1983. Salmonellosis cases (excluding typhoid fever) rose slightly in 1984, with 2,054 cases reported compared to 2,046 cases in 1983. There were 561 cases of shigellosis (bacillary dysentery) in 1983 with a decrease to 495 cases in 1984. Most shigellosis cases occurred in Essex County (161), Camden (48), and Monmouth (45).

The number of cases of mumps increased to 139 cases in 1984 compared to 129 cases in 1983. The majority of cases occurred in Atlantic County, which had 101 cases, followed by Camden County with 7 cases and Bergen County with 5 cases. Other diseases reported in 1984 included 90 cases of amebiasis, with 25 cases being reported in Cape May County, aseptic meningitis (294 cases), brucellosis (1 case), legionellosis (26 cases), malaria (41 cases), meningococcal infections (93 cases), pertussis (12 cases), tetanus (1 case), tularemia (1 case), typhoid fever (21 cases), typhus fever (3 cases), toxic shock syndrome (4 cases), encephalitis (arthropod borne) (1 case), and other encephalitis (24 cases).

NOTE: The reader's attention is directed to Section I, Communicable Diseases, in Health Statistics 1985, which will present an overview of AIDS in New Jersey.

HOSPITALIZATION IN NEW JERSEY

Overview

Data obtained from medical discharge abstracts are grouped into 20 categories. This report summarizes results for 11 of the 20 categories. Processing times required to collect, assemble and edit the medical discharge abstract data postpones the reporting of this information for 12 to 18 months. Thus, the following results typically lag by one year other data presented in this report.

Total Discharges

During calendar year 1983 there was a total of 1,220,260 discharges of patients from New Jersey acute care hospitals. This was a slight increase of 1.7% over 1982. It should not be assumed that total discharges represent only one admission per patient. Patients are sometimes readmitted because of complications that arise after discharge or because of a different illness. Of the total discharges, 941,543 or 77.16% represent one discharge for each patient. This was an increase of 1.4% over 1982. On the other hand, 17.1% of all discharges were associated with a readmission, a decrease of 17.7% from the 1982 level.

Referral Source

The question has often been asked--How do patients get into a hospital (by type of referral source)? The principal method was by direct physician's referral in 1983 or 63.7% of all cases compared to 55.9% for 1982. The second highest referral source was through the emergency room--31.3% for 1983 compared to 29.9% in 1982.

Admission Class

From 1982 to 1983 a modest increase of 8.7% occurred in the proportion of patients entering the hospital under emergency and urgent status (51.2%). Elective admissions decreased 3.5% since 1982.

Sex

Of the 1,220,260 discharges during 1983, 41.7% were male patients, while 58.3% were female patients. The ratio of female to male hospitalizations is higher because of maternity admissions. The difference in ratios between 1982 and 1983 was negligible.

Race

Whites accounted for 91.3% of all discharges, and Blacks accounted for 6.0%. None of the other race categories was above 1%.

Age

A complete breakdown has been tabulated for each individual age. However, to give a better comparative overview, an age cohort grouping for 5-year intervals was made. A review of the age groups based on five year intervals indicates that the 5 and under group, which includes infants, has the highest percentage (12.5%) of discharges. A slight but distinct shift toward increasing hospitalizations of older persons occurred from 1982 to 1983. Also there was a maternity use rate increase for ages 20 through 40.

Primary Services

The NJ/DOH has mapped the 99 designated classifications of clinical services provided by hospitals into 10 primary service groups. This mapping permits useful comparisons between medicine, surgery and other categories. In reviewing the 1982 and 1983 data a few shifts in relative frequencies occurred between categories. Medicine increased from 36.6% in 1982 to 40.4% in 1983. Pediatrics also showed an increase from 5.8% in 1982 to 7.5% in 1983. Newborns decreased from 7.8% to 5.1%.

Discharge Status

During 1983 92.7% of the patients were routinely discharged. Transfers to another facility or institution occurred in 3.4% of all discharges. Discharges against medical advice comprised 1.0%. Discharges of persons who expired were the same in 1982 and 1983 (2.9%).

Transfer Destination

When patients are discharged, they go home, to another facility or expire. By far, the majority of patients (97.2%) show no transfer destination, generally indicating that they have gone home. The same result was true for 1982. Transfers to long term care facilities, the second highest group, represented approximately 1.2% compared to 1.5% in 1982. Transfers to other acute care facilities (0.8% or 9,852) showed a significant decrease from 1982 (35,148 or 2.9%). Transfers to home health agencies were about one-quarter of a percentage (2839) for 1983, a decrease from 8,319 or 0.7% in 1982.

Primary Payer

The financial health of the hospital sector is determined by who is paying for health services. Even with New Jersey's case-based prospective payment system based on Diagnosis-Related Groups (DRGs), third party payers have variable schedules of reimbursement. Patients with Blue Cross coverage (34.3%) and Medicare insurance (28.6%) represented the greatest proportion of discharges in 1983 followed by commercial or private insurance coverage (14.1%) and Medicaid coverage (10.1%). Self-payers (7.3%) were the fifth largest type of primary payer.

Principal Causes for Hospitalization

In 1983 the three principal causes for hospitalization, single live births (92,789), delivery in a normal case (29,594), and heart failure (21,615) remained unchanged in rank order from 1982. However, in 1983 the fourth, fifth and sixth causes, namely cataract (18,492), acute myocardial infarction (17,974) and inguinal hernia (17,442) had been ranked in sixth, fifth and fourth places, respectively, in 1982.

In 1983 further changes occurred in the principal causes ranked eighth through tenth--pneumonia, organism unspecified (15,794), asthma (15,280), diabetes melitus (14,947), and cardiac dysrhythmias (14,192). These causes for hospitalization were ranked twelfth, eighth and thirteenth respectively in 1982.

Overall, in comparison to the 1982 list of the top ten principal causes for hospitalization, only two causes failed to make the 1983 top ten ranking - cholelithiasis, which placed twelfth with 14,152 hospitalizations, and other noninfectious gastroenteritis and colitis (13,445) which ranked fifteenth.

Note: Clinically active cases are those with a culture positive for *M. tuberculosis* or those on two or more anti-tuberculosis drugs. The count includes those with a previous episode of tuberculosis who have developed disease again if more than 12 months have elapsed since they were discharged from supervision. Non-clinically active cases were not included in the count if medication was not prescribed.

Rates for State Institutions and Military Posts are not computed due to lack of population base. The 1982 population estimates used for calculation of rates.

ACCIDENTAL DEATHS

INTRODUCTION

Accidental death data reporting for New Jersey have been collected and tabulated since 1968, through the use of the New Jersey Mortality reporting system. Accidental deaths are tabulated monthly and submitted to the National Safety Council as part of their overall reporting system. Data received from all the states are combined to prepare the National Safety Council's report, Accident Facts. Before the publication of this New Jersey accident report, no published summary of accidents for New Jersey had been released to the public. A number of special tables, however, were prepared and included in the prior releases of the New Jersey Public Health Reports.

The Accidental Death report herewith presents Total occurrence of death regardless of the victim's state of residency. Accidental deaths relating only to New Jersey as the residence of the accident victim has been included in the Mortality report. This report, accumulated deaths, provide an in-depth review of accidents by five major types of accident reported by the National Safety Council. The report further regroups the subdivision within each of the five types of accidents to present a better overview of accidents by their commonly referred to names and/or class; i.e. Motor Vehicles, Falls, Fires, Drowning, etc.

Historical statistics have been compiled covering the period from 1971 to 1984 by subdivisions of cause and age groups. All tables are presented in aggregated form with individual identifiers being removed prior to tabulation of data. It is believed that this report will provide an insight into accidental deaths and also give a new dimension in the area of New Jersey's Health Statistics reporting.

STATISTICAL OVERVIEW

Total Accidental Deaths

The term "accidents" covers most deaths from violent occurrences. Deaths from homicides and suicides, however, are excluded as are deaths for which none of these categories can be determined or deaths in war operations.

Total accidental deaths in New Jersey regardless of the residence of the victim, decreased in 1984 from the 1983 level of 2,310 to 2,265. This represents a decline of 2.0% over the year. Most of this decrease can be accounted for by 53 fewer motor vehicle accidents. Total accidental deaths at the national level increased in 1984 from the 1983 level of 91,500 to 92,000. This increase nationally represents a 0.5 percent rise of total accidental deaths. Motor vehicle deaths in the nation increased from 44,400 (0.6%) to 46,200 (4.1%).

New Jersey vs. National Accident Rate

In 1984, the New Jersey accidental death rate per 100,000 for state resident population was 27.9% down slightly from 28.5% in 1983. This rate is 28.5% lower than the national rate of 39.0% per 100,000 population for the same time period. An accident death rate for the State cannot be computed in total accidents because there is no known way to determine out-of-state population base.

Motor Vehicle Accidental Deaths

Motor vehicle deaths included those deaths involving mechanically or electrically powered highway transport vehicles in motion (except those on rails) and off the highway or street. Fatalities occurring in the State as the result of motor vehicle accidents dropped in 1984 by 5.1% from the 1983 level of 1,037 to 984. For the nation there was an increase of 4.1%. Of the 984 New Jersey deaths in 1984, 340 (or 34.6%) were the result of a collision with other motor vehicles; 273 or 27.7%, were caused by noncollision; 255 or 25.9% were classified as pedestrian deaths; 22 (or 2.2%) deaths resulted from a collision with a fixed object; 35 (3.6%) were listed as "injury to pedal cyclist" deaths, and one (0.1%) death was the result of collision with railroad train; 58 (5.9%) classified as Other and Unspecified deaths. All specified classifications of motor vehicle deaths decreased substantially in 1984 versus 1983 except "injury to pedal cyclist" which increased by 66.7% (or 14 deaths). While the drivers of motor vehicles represent the majority of the deaths that resulted in this classification, the records show that one out of every four motor vehicle accident deaths was a pedestrian.

Accidental Deaths in the Home

This category of accidents resulting in deaths includes deaths in the home and on the premises to occupants, guests, and trespassers. Also included in this category are domestic servants, but other persons working on home premises are excluded. The year 1984 recorded 532 accidental deaths in the home. This is an increase of 4.7% from the 1983 level of 508. The national total for 1984 was 20,000 deaths (same as in 1983) for a rate of 8.5% per 100,000 persons (compared to 7.1% per 100,000 persons in New Jersey). The ranking of New Jersey accidental deaths in the home for 1984 are as follows: The large majority, 77.6% of accidental deaths in the home occurred in falls, fires, and poisonings.

1984 ACCIDENTAL DEATH IN THE HOME

Type	Number	Percent
Falls	210	39.5
Fires	127	23.9
Poisonings (gas excepted)	76	14.3
Drownings	25	4.7
Suffocation (mechanical)	18	3.4
Suffocation (ingested food or object)	16	3.0
Firearms	15	2.8
Poisonings (by gases and vapors)	13	2.4
Other and Unspecified	32	6.0

Public Nonmotor Vehicle Deaths

Public accidents include deaths in public places or places used in a public way that do not involve motor vehicles. Most sports and recreational deaths are included in this category. Deaths in the course of employment are excluded. In 1984, there were 297 Public Nonmotor Vehicle deaths, a decrease of 8.9% from the 1983 total. Total deaths in this category decreased by 5% across the U.S. between 1983 and 1984, to approximately 18,500. In New Jersey, Falls tops the list with 66 (22.2%); in second place were Drownings, 64 (21.5%); followed by Air Transport, 33 (11.1%) and Water Transport, 19 (6.4%); Falls and Drownings are the areas of greatest concern in this classification of accidental deaths, accounting for almost one-half, (43.8%) of the total.

At Work

Work related deaths are those which arise out of and in the course of gainful employment regardless of where the accident occurs. Excluded from this category are work deaths to domestic servants, and deaths occurring in connection with farm chores that are classified as home deaths. Only 66 accidental deaths occurred in New Jersey's work settings in 1984, compared to 74 reported in 1983; this was a decrease of 10.8%. The national picture reflects a 1984 total of 11,500 deaths or a death rate of 11 per 100,000 workers (an 8.6% decrease since 1983). At work category, in 1984 for New Jersey death rankings are: (1) Service, 11, 16.7%; followed by construction with 9 deaths or 13.6%.

Overall Deaths - In Any Location or Setting

Another perspective can be obtained of accidental deaths by combining types or subcategory cause of deaths regardless of location of occurrence. This perspective permits accidental deaths to be measured as to the precise magnitude of the various types and causes. This insight can be achieved principally by combining like accidental deaths in the above categories into like groups: i.e. falls, fires, drownings, etc.

Aggregated and placed into a separate table using this grouping of accidental death rankings are as follows: (1) Motor Vehicle, 984, or 43.4%; (2) Falls, 276, or 12.2%; (3) Fires, 138 or 6.1%; (4) Drownings, 89 or 3.9%; (5) Poisonings, 89 or 3.9%; (6) Job Related, 66 or 2.9%; (7) Suffocations, 34 or 1.5%; (8) Air Transport, 33, or 1.5%; (9) Water Transport, 19 or 0.8%; (10) Firearms, 18, or 0.8%; (11) Railroad - not with motor vehicle, 14, or 0.6%; (12) Other and Unspecified, 119 or 5.3%; and (13) Unknown and Late Effects, 386, or 17.0%. A breakdown of the subcategory causes by age groups are presented in a table format at the end of this report.

Age Death Ratio Analyses

An analysis of accidental subcategory causes data by age shows that 59.3% of the motor vehicle accident deaths occur to persons between the ages of 15 and 44. Falls on the other hand, 73.9% happen to those persons 65 years of age and over. Drownings in 1984 show that 57.3% occurred to individuals between the ages of 15 and 44. Over one-fourth (26.5%) of the deaths by suffocation were children four years of age or less (up from 18.8% in 1983); Deaths by railroad -- not with motor vehicle indicate that 57.1% were in the 15-44 age group. The number of subcategory deaths by fires were fairly evenly distributed among all age groups, but in relation to population ratios of like age groups, children under 5 years of age, and adults 75 years of age and older, suffered a disproportionately higher share.

The three age groups that had a higher accidental death total ratio than their respective population ratios in 1984 are: (a) 15-24 years old, 20.1% to 16.2% (especially because of motor vehicle fatalities, followed by drownings); (b) the 65-74 year age group, 9.4% to 7.6%; and (c) those persons 75 years of age and over, 17.7% to 4.9% (the age group for which falls are a serious problem).

TABLE-1

**ACCIDENTAL DEATHS BY TYPE CLASSIFICATION
IN ANY LOCATION OR SPECIFIC SETTING
1983-1984**

Classification of Accident	1983		1984		Percent Change 1984 Vs. 1983

NATIONAL TRENDS IN POPULATION GROWTH

Past Patterns of Change

The pattern of population change by age is essentially a reflection of the fluctuation in the number of births over time, modified by changes in levels of immigration and mortality. Large fluctuations in fertility occurred during periods such as the Great Depression in the 1930's and the baby boom beginning in 1946. After sustaining a level of almost 3 million in the early to middle 1920's, the number of births dropped to 2.3 million by 1933-34 and did not return to their old levels until World War II.

In 1946-47, the year following the demobilization of the Armed Forces, the number of births reached a new plateau of 3.9 million, an increase of roughly a million over the previous year. Although the birth rate began to drop in the 1950's, the number of births exceeded 4 million for 11 successive years from 1953 to 1964. Births peaked at 4.35 million in 1960-61, but in no year between 1946 and 1971 did the number of births fall below 3.5 million. With the fertility decline of the 1970's, the level of births dropped to 3.1 million in 1973-74, and only in the 1980's has the number risen above 3.5 million again.

The population in the younger age groups (5 to 13 years) and school enrollment have reflected the long term decline in births since the middle 1960's. Elementary school enrollment plummeted during the 1970's, as the population in this age range declined by 17 percent, or 6 million from almost 37 million in 1970. This population has continued to decline moderately in the 1980's. With the rise in births since the middle 1970's, the population under 5 is growing again, so that stabilization and some small growth of the elementary school-age population can be expected soon. Constriction of the population 14 to 17 continues as the last of the baby boom generation passes through high school. That age group has declined by almost 8 percent since 1980, the largest decline of any age group. The college-age and young-adult population (18 to 24), which grew enormously during the 1960's and 1970's as the baby boom cohort entered it, has begun to decline since 1981.

The fastest growing age group in the United States in the 1970's, ages 25 to 34, increased by 3.8 million or 10.3 percent from 1980 to 1984. This age group will continue to grow during the 1980's but at a greatly reduced rate. By 1984, the oldest cohort of the baby boom had entered the 35-44 year age group, which has had the largest increase of any group since 1980 (5.0 million or 19.6 percent). This is the most rapidly growing age group and will continue to be for years to come, as the baby boom generation approaches middle age.

The population in ages 45 to 54 is beginning to decline, as the small Depression cohort ages. The age group from 55 to 64, which is now growing slowly, will begin to decline in size when the smaller cohorts of the late 1920's and the Depression enter the age group. By contrast, the elderly population (65 years and over) continues to grow rapidly, having increased as a group by 2.5 million or 9.8 percent since 1980 in the United States. The continued aging trend in the population is reflected in the change in the median age. Between 1980 and 1983, the median age rose 0.9 years, from 30.0 years to 30.9 years.

Although the general pattern of population change by age is approximately the same for Whites and Blacks, the Black population is growing more rapidly, as is apparent from the distinct racial differences in some age groups. The Black population under 5 years of age has shown significantly greater growth than the White population under 5. Similarly, each Black age group, with the exception of the 35 to 44 years and 65 years and over groups, exhibits either a larger increase or a smaller decrease than the comparable White age group. The overall effect is that the Black population grew by 5.3 percent, compared with 2.5 percent for Whites between 1980 and 1983.

The Census of 1980

The 1980 census established that dramatic changes took place in the social fabric of virtually every state during the 1970's. Shifts in family, household, and marriage patterns over the decade have altered the makeup of American society at the National, State, and local levels.

According to the 1980 census counts, the median age of the population increased to 30 years from the 28 years level reported in the 1970 Census. The increase has been attributed and was the result of declining fertility, aging of the "baby boom" cohorts, and increasing longevity of the population. Less than one-quarter of the population in 1980 was under 15 years of age and 11.3 percent were 65 years old and over.

The data for virtually all states points to faster growth of nonfamily households (one person or unrelated people in the same household) than families, smaller household size, and more families maintained by women with no husband present. These trends reflect a greater tendency of people to live alone, delay marriages, and separate and divorce. While families still make up 73 percent of all households, this is down from almost 90 percent indicated in the 1980 Census. The data also reveal variations in the composition of families among different race and Spanish origin groups.

NEW JERSEY POPULATION TRENDS

Overview

After the 1980 Census of Population and Housing results were in, New Jersey tabulated seven million plus inhabitants making it the ninth most populous state in the nation. With the highest density in the nation, at 986.1 persons per square mile as of April 1, 1980, it had fifteen times the density of the United States and almost three times that of the Middle Atlantic region. Already, the most densely populated state in the nation, New Jersey has now passed the 1,000 - person per square mile level (with a population density of 1002.6 persons per square mile as of July 1, 1984). Rhode Island was a distant second, at 911.8 persons per square mile, as of July 1, 1984. State population density figures, while correctly stating the population to land ratio do not, however, reflect the whole picture. Density is not uniform within the State, it varies considerably from county to county and from municipality to municipality.

The southern counties of New Jersey (Salem, and Cumberland), as well as those in the northwest (Hunterdon, Sussex, and Warren), all have population densities under three hundred per square mile. This is in marked contrast to the counties of Hudson and Essex respectively which have upward to twelve and seven thousand persons per square mile. It is the State's northern area where the four largest cities are located and the concentration of population is the highest.

Growth Trends

Back during the decades of the 1950's and 1960's, the State's population expanded rapidly, growing at an average annual rate of 2.3% from 1950 to 1960 and 1.7% from 1960 to 1970, compared to the national rates of 1.8% and 1.3%. The State's population "boom" came at the time when the Middle Atlantic states were experiencing far slower growth rates. The trend reversed, however, and has gripped the State since 1973. Population actually decreased during the 1973-1977 period. The average annual increase was only 0.2% for the decade, as compared with 0.9% for the United States. The net change for New Jersey between the Census period 1970-1980 indicated a 2.5% overall increase, while the nation as a whole increased by 11.4%.

Source of Change

The population growth is made up of two major components. The first classified as Natural Increase comprises births minus deaths. The second is termed Net Migration which is an inward movement of new residents minus outward movement. It is interesting to see how New Jersey's growth patterns relate to the Natural Increase part of change almost paralleling that of the United States, while net migration was from the north and central region of the country to the warmer southern and southwestern regions.

A review of the State's birth rate shows that New Jersey historically had a lower birth rate than the United States. Birth rates have declined substantially in the past thirty years both nationally and in New Jersey. New Jersey's death rate was also slightly higher than the national average during the 1950's and early 1960's, but since the mid sixties the rates have been virtually identical. The leading cause of death in both New Jersey and the nation as a whole, have consistently been heart disease, which in 1984 claimed 365.4 persons per 100,000 residents. Cancer, the second leading cause accounted for 221.7 deaths per 100,000 New Jersey residents as it continued to climb, in the highest rate per 100,000 thus far recorded.

Net Natural Increase

With the major component of Population growth being Net Natural Increase, it is a logical conclusion that births and deaths should have a strong influence on future growth and growth patterns within New Jersey. Nationally, as well as in the State, the net natural rate of increase has been falling since birth rates have declined faster than death rates. Moreover, New Jersey's net natural rate of increase has been below the national average for the past three decades because of a lower birth rate and a similar or higher death rate. From 1970 through 1984, for instance, New Jersey's annual net natural increase averaged about 0.47% as compared to .98% for the United States. Since 1980 nationally however, the birth history tends to show a decrease from 1980 to 1984; the National rate moved from 15.9 to 15.7. The death rate in the U.S. remained more constant at 8.8 deaths per 1,000 population in 1980 and 8.7 deaths per 1,000 population in 1984. In New Jersey the birth rate rose from 13.1 per 1,000 population in 1980 to 13.4 per 1,000 population in 1984 while the death rate remained relatively constant (at 9.3 per 1,000 population in 1980 and 9.2 per 1,000 population in 1984).

Migration Rate

The other factor influencing population growth Net migration during the 1950's and 1960's recorded a movement from New York and Pennsylvania to New Jersey's growing suburbs. New Jersey's average annual net migration rate of 1.13% for 1950-1960 was nearly seven times the nation's 0.17% average annual rate. The State's 1960-1970 annual rate of: 78%, likewise, was considerably higher than the national annual average, which remained at 0.17%. This influx of population explains most of New Jersey's rapid growth from 1950 to 1970.

New Jersey's in-migration slowed in the seventies, especially during the recession periods of 1970 and 1974/75. In fact, more people left the State than entered, with an average net migration rate of about 0.2% annually, compared to a national gain of 0.2%. This reversal in the State's net migration trend explains to a degree the slowing and the decline that has taken place within the State in the late seventies. This rate of out-migration slowed, was confirmed by the 1980 Census. New Jersey's net in-migration rate was 0.3%. While this 0.3% is lower than the national rate of 1.0% for the same time period, it is a marked reversal from the net out-migration New Jersey was experiencing in the 1970's.

Intrastate Differences

Total New Jersey populations increased by only 2.0% between 1980 and 1984. In 1984, births outnumbered deaths by approximately 32,000 and out of State migration exceeded in-migration by about 5,000. Internal shifts were similar and not unlike demographic trends found nationwide. Older cities continued to lose not only its manufacturing base but its residents who went to seek greener pastures elsewhere. Suburbia remained relatively stable and continued to move outward with a greater radius from center cities, new "exurbs" grew. In relatively rural counties of southern New Jersey, near the shore, large retirement communities were established.

The State's six largest cities (Newark, Jersey City, Paterson, Elizabeth, Trenton and Camden) remained virtually unchanged between 1980 and 1984 ranging from an average annual percent change of +0.31% increase in Elizabeth and a 0.81% decrease in Newark. The counties with the greatest population decrease between 1970 and 1980 were three urban counties, Essex, Hudson and Union, each with 7 to 9% decreases. Atlantic City, with its new gambling casinos is one of the "Tourist" cities throughout the United States that have been able to show to some degree, a reversal in urban economic decline trend. However, while the result has been increased employment, this has not altered the total numbers in resident population. People who came to Atlantic City for the new jobs generated by casino growth, for a variety of reasons, did not establish residence inside the city limits. In part, land values increased prohibitively from the standpoint of residential availability and the land purchased by hotels and casinos was for commercial development and not residential in nature.

The most notable population changes in this State in the decade between 1970 and 1980 were the growth of four relatively rural counties. Hunterdon's population increased 25%; Cape May's 38%; Sussex' 50%; and Ocean County 66%. Three of these four counties (Hunterdon, Cape May and Sussex) were among the five lowest in population in the State both in 1970 and 1980. In two of these counties, Cape May and Ocean, growth can be attributed to a large increase in retirement communities. In Hunterdon, the age structure of the population in 1980 was very

similar to the State as a whole. In Sussex, the age structure shows a larger number of younger families. The age structure in each of the counties and in the State is presented in Table 3.

Since 1980, Ocean County is estimated to have grown by the largest amount: approximately 25,200 persons or 7.3%. Cape May had the top growth rate between 1980 and 1984 of 1.85% per year, which is only slightly greater than half of its annual growth rate for the period 1970-80. By contrast, the two largest counties in the State, Bergen and Essex, are the only ones that have declined in numbers. Since 1980 Essex's population decreased by 9,800 persons and Bergen by 800 persons.

Racial Composition

The racial composition of the New Jersey population closely resembles that of the United States as it has in the past. The 1960 Census data reported 91.3% of New Jersey's population was white, as compared to 88.6% for the United States. By 1980 the white composition represented 83.2%. New Jersey's black population increased from 8.5% to 16.8% of the population over the past twenty-year period from 1960 to 1980. In the nation the increase for the same period was from 10.5 to 11.7.

Age Distribution

The State's population is slightly "older" than the nation's. The age distribution of the State's population has changed markedly over the years. The decline of the birth rate and the decreasing death rate have decreased the percentage of "future workers" in the population, while enlarging the top end of the age structure. In 1960, 29.0% of New Jersey's population was under fifteen years of age, but by 1970 this group accounted for only 27.8% of the population, by 1980 percentage wise those under 15 represented 21.4% and by 1984 those under 15 years of age represented 20.2%. The disparity increases for the portion of the population under ten; in 1960, 20.3% of the population was ten and under, 1970 only 17.9%, in 1980, 13.2% and in 1984, 12.8%. At the upper end of the age distribution, the share of population 65 and over has increased from 9.1% in 1960 to 9.7 in 1970; the 1980 census shows a further increase to 11.7% and in 1984 persons over age 64 represented 12.5%. The New Jersey trends parallel those of the United States as a whole and could have serious implications in the next ten to twenty years as a declining working-age population will have to support an increasingly large number of elderly. The impact on our medical establishment likewise will be profound.

Marriage and Divorce

During the seventies the marriages decreased with the exception of 1972 and 1973 which gave an indication of an upturn that did not materialize. The bottom was reached in 1977 and since then an upturn thus occurred. Marriage rates have increased in recent years even though women have increasingly chosen careers over marriage, the postponement of marriage to establish a career. Nationally, marriage rates decreased and appears to have reached its peak from 11.1 per 1,000 population in 1950 to 10.8 in 1980. New Jersey did not reflect the national trend. The State's marriage rate which was a low 6.5 in 1959 rose to 7.6 in 1980 and reached 8.3 in 1983. Divorce rates have increased significantly both in New Jersey and the nation during the past thirty years. New Jersey's 1984 rate of 3.8 divorces per 1,000 population, though one of the lowest in the nation was more than 2.7 times the 1970 rate.

1984 POPULATION

Overview

New Jersey's population was estimated at 7,515,000 as of July 1, 1984 -- up by 150,000 or 2.0% from the census count on April 1, 1980. Although substantially less than the U.S. gain of 4.2%, New Jersey outpaced the other seven most populous states in the Northeast and North Central Regions, including New York and Pennsylvania.

New Jersey's Comparative Growth

Although New Jersey's annual rate of population increase since 1980 (0.47% per year) was less than half of the national gain (0.98% per year), state growth was about twice the increase shown in New York. Pennsylvania showed virtually no change at all. Of the eight largest states (over 5 million) in the Northeastern and North Central Regions, not only did New Jersey lead in the percent increase, but it was second only to New York in absolute growth since 1980.

A primary reason for New Jersey's growth was that it had positive net migration; that is, twenty-five thousand more people moved into New Jersey than moved out from 1980 to 1984. New Jersey was the only state among the "Big Eight" in the Northeast and North Central Regions with this distinction.

TECHNICAL NOTES

SOURCES OF DATA

Vital Events

Birth, death, fetal death, and marriage certificates are the basic source documents used for data on vital events of New Jersey residents during the calendar year as stated. Birth and fetal death certificates are usually completed by hospital personnel, physicians, and funeral directors. Copies of certificates are available from the Vital Statistics and Registration Program. Divorce and annulment data are compiled from transmittal documents which are received from records maintained by the Office of the Administration of the Courts. Abortion data are compiled from a Special Department of Health form received monthly from all facilities (hospitals and clinics) licensed to perform abortions.

The cut-off date for the vital events data in this report was August 1. Any data pertaining to an event for which a certificate was filed after that date, are not included. It is possible that future data obtained from the NJ/DOH may differ slightly from that which appears on this report. If this should occur, it is because an update was made to the data year after the cut off date.

Birth and Death events relating to New Jersey residents which occurred in another state are included in this report, as part of the resident counts. The inclusion of these data are made possible by an agreement among all registration areas in the United States for resident exchange of copies of certificates. No marriages, divorce, or abortion reports are included in the inter-state vital statistics exchange program. Accident data are generated from the Death records. Fertility data are derived through the use of birth data and population characteristics (race, age and sex) reported in the 1980 Census of Population and Housing) conducted by the U.S. Bureau of Census. U.S. data was taken from the Monthly Vital Statistics reports released by the National Center for Health Statistics and/or Current Population Reports, U.S. Bureau of Census.

Population

The population data used in this publication are based in part on data collected by census enumerators during the 1980 Census of Population and Housing, and released by the Bureau of Census. Every person and housing unit was renumerated on a questionnaire that requested certain basic demographic information, such as age, race, and relationship. Established as the base year, 1980 provided the levels and characteristics for the annual estimates reported and released by the NJ Department of Labor, Office of Demographic and Economic Analysis.

Abortions

The New Jersey Abortion Surveillance is a health monitoring system conducted by the Center for Health Statistics within the New Jersey Department of Health. Reporting forms are completed by abortion providers and are coded and processed by the NJ/DOH on a monthly basis.

Morbidity

There are two sources of Morbidity data in New Jersey. The one that has been readily available in the past is Reportable Communicable Diseases. These data are collected by various programs throughout the Department in surveillance activities. Communicable diseases are required by law to be reported to the Department of Health. The other source of morbidity data pertain to hospitalization and treatment. With the development and implementation of the Diagnostic Related Groups (DRGs), the Department in 1976 implemented a program to collect both primary and secondary diagnosis, as related to the principal cause of hospitalization. These data are submitted to the NJ/DOH quarterly and are analyzed annually.

DATA QUALITY

Vital Events

The quality of data presented in this report is directly related to the completeness and accuracy of the information contained on the certificates, and corrected through a direct query program. The NJ/DOH works to ensure that the information received is as complete and accurate as possible, and maintains two major program operations related to improving the quality of information received on certificates.

The query program is a system used to follow back with local registrar, with hospital personnel, funeral directors, and/or physicians, concerning incomplete or conflicting information. The follow-back contact is usually done by telephone, and is based both on a manual and computer editing procedure.

The field program attempts to improve certificate information by educating the participants in the vital registration system; i.e. hospital personnel, funeral directors, local registrars, physicians, etc. of the uses and importance of vital statistics data. This is accomplished by conducting seminars with direct participation of the type of individuals listed above, and with various associations. In addition to regularly scheduled seminars, the NJ/DOH field representative makes site visits when problems with registration relating to a particular area or institution are discovered.

The National Center for Health Statistics (NCHS) monitors New Jersey's coding of Birth and Death data. NCHS has established a two percent upper limit for coding difference involving any one item, with the exception of cause of death. A five percent limit is established for this item because of the complexity of the coding process.

Population

While it is impossible to completely eliminate error from an operation as large and complex as the 1980 census, the Bureau of the Census attempted to control such errors during collection and processing operations through record checks and re-checks, post-enumeration follow-back, processing quality control checks, and installation of special coding procedures for nonresponses to questions on the census questionnaire.

Abortions

Abortion data collected do not imply the complete and comprehensive status of legal abortion in New Jersey. The quality of the data is dependent on the completeness and accuracy of the information supplied by providers of abortion services within the State. The Center for Health Statistics undertakes computer edits on all data submitted and makes applicable changes for obvious errors. Queries are made to the providers to correct the abortion information and to correct detected errors and incomplete documents.

Morbidity

Reportable diseases are monitored for completeness by the Communicable Disease program under the Division of Epidemiology and Disease Control. A tracking system is in place that checks and double checks on the information. All data are actual counts.

Two measurements are used in assessing the accuracy and quality of the Medical Discharge Abstract data. The first relates directly to the data contents of the tapes submitted which are evaluated for completeness as to error, consistency, and overall error tolerance levels. All errors detected are reviewed and levels of severity established in terms of rates on the data that are received. The second measure is the completeness and correct coding. This comparison is related to a direct comparison of the records maintained by the facility and abstract data submitted to the Department.

GEOGRAPHIC ALLOCATION

Vital Events

Vital events can be classified geographically in two ways. The first way is by place of occurrence; i.e. the actual state, county and minor civil division (MCD) in which the birth or death took place. The second, and more customary way is by place of residence; i.e. the state, county and MCD given to the usual residence of the mother, in the case of a newborn, or the decedent in the case of death. Fetal deaths and infant deaths in cases where the child was never discharged from the hospital, are classified to the residence of the mother.

While occurrence statistics are accurate and have both administrative value and statistical significance, residence statistics are by far the more useful tool, when constructing health indices for planning and evaluation purposes. Likewise, Vital Statistics residence data are used to determine the "Natural Increase" component of the state's population estimates. The statistics provided in this report are residence data, unless otherwise stated.

It should be noted that the allocation of vital events by place of residence is sometimes difficult. This is because classification depends entirely on the statement of the usual place of residence furnished by the informant at the time the original certificate is completed. For various reasons, this statement may be incorrect or incomplete. For example, mailing addresses often differ from the actual geographic residence.

Where the mailing address of an unincorporated or local name place is given as the place of residence, it is sometimes impossible to allocate the event to a specific or the correct MCD. How often incorrect information on residence is recorded is not known, but it is generally because of the lack of information concerning the exact location of residence or misunderstanding of the question on the part of the informant. Postal Zip Codes are used for cross reference in cases where allocation is required if at all possible. Every attempt is made to code the correct residential location. This problem is applicable generally only to MCD level data. Resident counts for the state as a whole are accurate. County resident figures, likewise, have been verified and are substantially correct and can be used with a high degree of confidence.

Population

The error associated with allocation of event to area of residence is almost nonexistent, since the 1980 Census of Population and Housing involved on-site enumeration of both population and housing units. County boundaries legally defined and in effect as of January 1, 1980 were recognized in the 1980 census. Census data are also available from the NJ/DOL Office of Demographic and Economic Analysis, for geographic areas not represented in this publication, such as census tracts and enumeration districts. Townships that are all incorporated in the state of New Jersey, are also considered as MCDs.

Abortions

County of residence of the abortion recipient is recorded on the reporting form submitted to the NJ/DOH. The geographic data are only as accurate as the information given by the patient at the time of the procedure. No verification is made on questions asked of the patient. A Postal Zip Code notification program has been installed into the computer/edit phase to verify and correct, if possible.

Since the New Jersey abortion surveillance began, New Jersey residents have comprised 78 to 85% of all reported abortions, performed at in-state facilities. The NJ/DOH is unable at this time to obtain detailed data on New Jersey residents receiving abortion in other states or at physician's offices. The resident data compiled by the Center for Health Statistics include only those data on residents receiving abortions at licensed facilities within the State.

Morbidity

A strict control is maintained over the geographic location and coding for both reportable diseases and Discharge Abstract data. Evaluation systems have been developed to insure correct reporting of resident codes. Likewise, a Postal Zip Code verification program has been installed into the computer edit phase of the system to verify and correct if possible.

DEFINITION OF RATES

Absolute counts of health-related events do not readily lend themselves to analysis and comparison between years and various geographic areas because of population differences. These demographic differences include total number, age, and sex distributions, and ethnic or racial differentials. In order to assess the health status of a particular population at a specified time, the absolute number of events is converted to a relative number, such as a probability of living or dying, a rate, a ratio, or an index. This conversion is made by relating the crude number of events to the living population at risk in a particular area at a specified time.

In interpreting the conditions described by vital statistics rates, considerable caution must be observed. In particular, differences in rates from time to time or place to place may arise from a number of population differences and other confounding factors, and appropriate techniques (such as standardization) should be utilized in such comparisons. This factor has been taken into account in developing the rates used herewith.

Please note that some of the tables giving cause of death data were modified in 1979 to accommodate changes resulting from the adoption of a revised cause of death coding scheme, as set forth in The Ninth Revision of the International Classification of Diseases (ICD-9CM). The vast majority of cause of death categories, however, remain comparable with previous years' tables. Changes in definitions of rheumatic heart disease, nephritis and nephrosis, and hypertension, heart, however, between the Eighth Revision of the ICD and the Ninth Revision, has caused noticeable differences in the numbers of deaths attributed to those categories between 1978 and 1979 when ICD-9 went into effect.

The 1980 Census of Population and data was obtained from data released in Summary Tape File 1A (STF-1A) for New Jersey by the Office of Demographic and Economic Analysis, Department of Labor. Annual New Jersey population estimates are based on federal control totals developed jointly with the assistance of the NJ Department of Labor. All rates used in this report were developed using a projectional rate distribution after adjustments were made to account for the Natural Increase (of births minus deaths). The NJ/DOH only estimates essential population characteristics associated with New Jersey as age cohort totals by county by sex. The age, sex, and race estimates used as the basis for the rates were developed by the Center for Health Statistics using the "Proportionate Share Technique" controlled to the July 1, 1981 population estimates produced by the Department of Labor. These are crude estimates and were generated only to have a base from which to calculate rates.

DESCRIPTIVE STATISTICS

RATES, RATIOS, PROPORTIONS, AND INDICES

- A. RATE: A rate measures the frequency of occurrence of some particular event. A rate is of the form:

$$\frac{x}{y} \times k$$

where

- x = number of times an event has occurred during a specific interval of time.
- y = number of persons exposed to the risk of the event during the same interval.
- k = some round number (100; 1,000; 10,000; 100,000; etc.) or base, depending upon the relative magnitude of x and y.
1. MORBIDITY RATES: Morbidity rates measure the frequency of illness within specific populations. Time and place must always be specified. The most commonly used morbidity rates include point prevalence, period prevalence, incidence, and attack rate as shown in Table E.
- a. PREVALENCE: Prevalence measures the frequency of all current cases of disease (old and new) and is of two types:
- (1) POINT PREVALENCE: Point prevalence measures the frequency of all current cases of a disease (old and new) at a given instant in time.
 - (2) PERIOD PREVALENCE: Period prevalence measures the frequency of all current cases of disease (old and new) for a prescribed period of time.
- b. INCIDENCE: Incidence measures the rapidity with which a disease occurs or the frequency of addition of new cases of a disease. These new cases of disease occur either through onset of the disease on current members of the population or by immigration of persons already ill into the population. Incidence is always calculated for a given period of time.
- c. ATTACK RATE: An attack rate is an incidence rate usually expressed as a percent, used for particular populations, and observed for limited periods of time, as in an epidemic.

2. MORTALITY RATES: Mortality rates measure the frequency of deaths within specific populations and are calculated for a given time interval and place. Several general and specific formulae are used to describe mortality as shown in Table E.
3. NATALITY RATES: Natality rates measure the frequency of births (birth rates) and the probability of births (fertility rates) within specific populations and are calculated for a given time interval and place. Some frequently used natality rates and ratios are shown in Table E.

B. RATIO: A ratio is the expression of the relationship between a numerator and denominator which may involve either an interval in time or may be instantaneous in time. The ratio is of the form:

$$x : y \quad \text{or} \quad \frac{x}{y} \times k$$

where

x = number of events or items counted and not necessarily a portion of y.

y = number of events or items counted and not necessarily a population of persons exposed to the risk.

k = a base, as in the case of a rate, but usually 1 or 100 for the purposes of expressing ratios.

C. PROPORTION: A proportion is an expression in which the numerator is always included in the denominator, and the base is equal to 100. Therefore, a proportion is always expressed as a percent.

D. INDEX: An index is the best available approximation to a true rate. This usually occurs when we are unable to count directly the number at risk (denominator) and use something else which we can count to give us an impression of the number at risk.

Thus, for example, in order to calculate a maternal mortality rate, we should, strictly speaking, divide the number of deaths assigned to deliveries and complications of pregnancy, childbirth, and the puerperium by the total number of pregnancies occurring in a specified time interval. Since we are unable to count the total number of pregnancies, we replace this by the number of registered live births in order to obtain an estimate of the number of pregnancies. The resulting maternal mortality rate is therefore not a rate at all in the strict sense, but is nevertheless a useful *index* which gives an impression of the risk of dying associated with pregnancy.

TABLE A

FREQUENTLY USED RATES, RATIOS, PROPORTIONS, AND INDICES
USED FOR DESCRIBING NATALITY, MORBIDITY, AND MORTALITY

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
1.	<p style="text-align: center;"><u>NATALITY</u></p> <p><u>Birth Rate</u></p> <p>Crude; specific for age of mother, sex of child, socioeconomic status, etc.</p>	Number of live births reported during a given time interval	Estimated mid-interval population	1,000
2.	<p><u>Fertility Rate</u></p> <p>(a) <u>Theoretical Purposes</u></p> <p>(b) <u>Current Usage</u></p> <p>Crude; specific for age of mother, race, socioeconomic status, etc.</p>	<p>Number of live births reported during a given time interval from mothers aged 15-44 years</p> <p>Number of live births reported during a given time interval</p>	<p>Estimated number of women in age group 15-44 years at mid-interval</p> <p>Estimated number of women in age group 15-44 years at mid-interval</p>	1,000
3.	<p><u>Low Birth Weight Ratio</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	Number of live births under 2,500 grams (or 5½ lbs.) during a given time interval	Number of live births reported during the same time interval	100

TABLE A (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
4.	<p style="text-align: center;"><u>MORBIDITY</u></p> <p><u>Incidence Rate</u></p> <p>Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.</p>	<p>Number of new cases of a specified disease reported during a given time interval</p>	<p>Estimated mid-interval population</p>	<p>Variable: 10^x where $x = 2, 3, 4,$ $5, 6$</p>
5.	<p><u>Attack Rate</u></p> <p>Crude by cause; specific for age, race, sex, socio- economic area, etc.</p>	<p>Number of new cases of a specified disease reported during a specific time interval</p>	<p>Total popula- tion at risk during the same time interval</p>	<p>Variable: 10^x where $x = 2, 3, 4,$ $5, 6$</p>
6.	<p><u>Point Prevalence Rate</u> <u>(Ratio)</u></p> <p>Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.</p>	<p>Number of current cases, new and old, of a specified disease existing at a given point in time</p>	<p>Estimated popu- lation at the same point in time</p>	<p>Variable: 10^x where $x = 2, 3, 4,$ $5, 6$</p>
7.	<p><u>Period (Case-Load)</u> <u>Prevalence Rate</u> <u>(Ratio)</u></p> <p>Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.</p>	<p>Number of current cases, new and old, of a specified disease occurring during a given time interval</p>	<p>Estimated mid-interval population</p>	<p>Variable: 10^x where $x = 2, 3, 4,$ $5, 6$</p>

TABLE A (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
8.	<p style="text-align: center;"><u>MORTALITY</u></p> <p><u>Crude Death Rate</u></p> <p>Crude; specific for age, race, sex, socioeconomic area, etc.</p>	Total number of deaths reported during a given time interval	Estimated mid-interval population	1,000
9.	<p><u>Cause-Specific Death Rate</u></p> <p style="text-align: center;">or</p> <p><u>Cause of Death Rate</u></p> <p>Crude by cause; specific for age, race, sex, socio-economic area, etc.</p>	Number of deaths assigned to a specific cause during a given time interval	Estimated mid-interval population	100,000
10.	<p><u>Cause-Specific Death Ratio</u></p> <p style="text-align: center;">or</p> <p><u>Cause of Death Ratio</u></p> <p style="text-align: center;">or</p> <p><u>Proportional Mortality Ratio</u></p> <p>Crude by cause; specific for age, race, sex, socio-economic area, etc.</p>	Number of deaths assigned to a specified cause during a given time interval	Total number of deaths from all causes reported during the same interval	100 or 1,000
11.	<p><u>Case Fatality Rate (Ratio)</u></p> <p><u>Death-to-Case Ratio</u></p> <p>Crude; specific for age, race, sex, socio-economic area, etc.</p>	Number of deaths assigned to a specified disease during a given time interval	Number of new cases of that disease reported during the same time interval	100

TABLE A (continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
12.	<p>(a) <u>Fetal Death Rate I</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	<p>Number of fetal deaths of 28 weeks or more gestation reported during a given time interval</p>	<p>Number of fetal deaths of 28 weeks or more gestation reported during the same time interval plus the number of live births occurring during the same time interval</p>	<p>1,000</p>
	<p>(b) <u>Fetal Death Rate II</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	<p>Number of fetal deaths of 20 weeks or more gestation reported during a given time interval</p>	<p>Number of fetal deaths of 20 weeks or more gestation reported during the same time interval plus the number of live births occurring during the same time interval</p>	<p>1,000</p>
13.	<p>(a) <u>Fetal Death Ratio I</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	<p>Number of fetal deaths of 28 weeks or more gestation reported during a given time interval</p>	<p>Number of live births reported during the same time interval</p>	<p>1,000</p>
	<p>(b) <u>Fetal Death Ratio II</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	<p>Number of fetal deaths of 20 weeks or more gestation reported during a given time interval</p>	<p>Number of live births reported during the same time interval</p>	<p>1,000</p>

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
16.	<p><u>Neonatal Mortality Rate</u></p> <p>Crude; specific for race, sex, socioeconomic area, birth weight, cause of death, etc.</p>	<p>Number of deaths under 28 days of age reported during a given time interval</p>	<p>Number of live births reported during the same time interval</p>	<p>1,000</p>
17.	<p><u>Postneonatal Mortality Rate</u></p> <p>(a) <u>Theoretical Purposes</u></p> <p>(b) <u>Current Usage</u></p> <p>Crude; specific for race, sex, socioeconomic area, cause of death, etc.</p>	<p>Number of deaths from 28 days of age up to, but not including, 1 year of age, reported during a given time interval</p> <p>Number of deaths from 28 days of age up to, but not including, 1 year of age, reported during a given time interval</p>	<p>Number of live births reported during the same time interval less the number of deaths under 28 days of age</p> <p>Number of live births reported during the same time interval</p>	<p>1,000</p> <p>1,000</p>
18.	<p><u>Maternal Mortality Rate</u></p> <p>Crude; specific for age of mother, race, socioeconomic area, etc.</p>	<p>Number of deaths assigned to causes related to pregnancy during a given time interval</p>	<p>Number of live births reported during the same time interval</p>	<p>10,000</p>

NOTE: This section was taken from: Vital and Health Statistics Techniques of Community Health Analysis, Published by Center for Disease Control, U.S. Department of Health and Human Services

**STATISTICAL FORMULAS USED IN COMPUTING BIRTH,
DEATH AND MORBIDITY RATES**

Crude Birth Rate - Expressed per 1,000 population.

$$\frac{\text{No. of Live Births}}{\text{Midyear population estimates}} \quad \times 1,000$$

Fertility Rate - The number of live births to women aged 15-44 per 1,000 women in the same age group.

$$\frac{\text{No. of Live Births to Women Aged 15-44}}{\text{No. of Women aged 15-44}} \quad \times 1,000$$

Crude Death Rate - Expressed per 1,000 population.

$$\frac{\text{No. of Deaths}}{\text{Midyear population estimates}} \quad \times 1,000$$

Infant Mortality Rate - Expressed per 1,000 live births.

$$\frac{\text{No. of Deaths Under 1 Year}}{\text{No. of Live Births}} \quad \times 1,000$$

Neonatal Mortality Rate - Expressed per 1,000 live births.

$$\frac{\text{Infant Deaths under 28 days}}{\text{No. of Live Births}} \quad \times 1,000$$

Fetal Death Rate - Expressed per 1,000 live births.

$$\frac{\text{No. of Fetal Deaths}}{\text{No. of Live Births}} \quad \times 1,000$$

Perinatal Mortality Rate - Expressed per 1,000 total deliveries (live births plus fetal deaths).

$$\frac{\text{No. of Deaths under 28 days + Fetal Deaths}}{\text{No. of Live Births + Fetal Deaths}} \quad \times 1,000$$

Maternal Mortality Rate - Expressed per 10,000 live births.

$$\frac{\text{No. of Maternal Deaths}}{\text{No. of Live Births}} \times 10,000$$

Specific Cause-of-Death-Rate - Expressed per 100,000 population.

$$\frac{\text{No. of Deaths from a Specific Disease}}{\text{Midyear Population Estimate}} \times 100,000$$

Age-Specific Rates - Expressed per 100,000 population in a specified age group.

$$\frac{\text{No. of Deaths in a Specific Age Group}}{\text{Estimated Population in the Same Age Group}} \times 100,000$$

Morbidity Rate - Expressed per 100,000 (10,000 or 1,000) population

$$\frac{\text{No. of Reported Cases of a Given Disease}}{\text{Midyear Population Estimate}} \times 100,000$$

DEFINITIONS

<u>ABORTION</u>	premature expulsion or removal from the uterus of the products of conception (the embryo or nonviable fetus).
<u>ACCIDENT</u>	that occurrence in a sequence of events which usually produces unintended injury, death or property damage.
<u>ACCIDENT TYPE</u>	describes the occurrence leading to injury or property damage.
<u>AGE-SPECIFIC MORTALITY RATE</u>	the number of deaths of a given age group per 100,000 estimated persons in that age group usually expressed as an annual rate.
<u>AGENCY OR AGENT</u>	the principal object such as tool, machine or equipment in the accident and is usually the object inflicting injury or property damage.
<u>APGAR SCORE</u>	composite measure used to evaluate the newborn infant's general condition. Apgar scores are given one and five minutes after birth. Heart rate, respiratory, effort, color, muscle tone and reflexes are checked and evaluated. Each factor receives a score of 0, 1, or 2 and the sum of the five values is the overall score. A score of ten is optimum.
<u>ASSOCIATED CAUSE OF DEATH</u>	condition other than the underlying cause of death which may have contributed to the death.
<u>BIRTH RATE</u>	the number of live births per 1,000 population.
<u>BIRTHWEIGHT</u>	weight of fetus or infant at time of delivery (normally recorded in pounds and ounces or in grams).
<u>CAUSE GROUP</u>	a summary of deaths resulting from or cases of, related diseases as defined by the International Classification of Diseases Adapted For Use in the United States, published by the U.S. Department of Health, and Human Services; usually specified by a series of 3-digit codes; i.e. 140-208 malignant neoplasms.
<u>DAY</u>	(motor-vehicle accidents) is the time interval between sunrise and sunset.

DEATH RATE

the number of deaths per 100,000 population.

DEATH FROM ACCIDENT

a death which occurs within one year of the accident.

DELIVERIES

live births plus reported fetal deaths.

DISABLING INJURY

an injury causing death, permanent disability, or any degree of temporary total disability beyond the day of the accident.

ESTIMATED POPULATION

the estimated number of persons in a given group based on the latest census data and adjusted for annual births, annual deaths and net migration.

FATAL ACCIDENT

an accident which results in one or more deaths within one year.

FERTILITY RATE

the number of live births to women aged 15-44 per 1,000 women in this age group, usually expressed as an annual rate.

FETAL DEATH

death prior to the complete expulsion or extraction from its mother of a product of conception; the fetus shows no signs of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

FETAL DEATH RATES

the number of fetal deaths occurring in the twentieth week of gestation or later (required by law to be registered as fetal deaths) per 1,000 live births, usually expressed as an annual rate.

FIRST TRIMESTER

first twelve weeks of pregnancy, as determined by the history given by the patient considered in conjunction with the physician's estimation of length of pregnancy by clinical examination of the size of the uterus (NJAC 8:40-4.1).

HOME

a dwelling and its premises within the property lines, including in addition to the usual single-family dwellings and apartment houses, duplex dwellings, boarding and rooming houses and seasonal cottages. Excluded from Home are barracks, dormitories, and resident institutions.

<u>HOMICIDE</u>	the act of one person who kills another, includes deaths from injuries purposely inflicted by other persons, deaths from injuries resulting from intervention by law enforcement officers and deaths caused by legal execution.
<u>HOSPITAL</u>	health care facility licensed as a hospital in accordance with the statutes of New Jersey.
<u>HYSTERECTOMY</u>	excision of the uterus.
<u>HYSTEROTOMY</u>	incision of the uterus to remove the fetus before viability.
<u>ILLEGITIMATE BIRTHS</u>	a birth to an unwed woman, or to a woman whose husband did not father the infant.
<u>ICD 9 CODE</u>	a listing of disease classifications known as the "Ninth Revision International Classification of Diseases Adapted for Use in the United States," published by the United States Department of Health and Human Services, used in the statistical coding and tabulation of specific disease morbidity and mortality.
<u>IMMATURE BIRTH</u>	a live birth weighing 2,500 grams, (5 Lbs. 8 oz., or less).
<u>INCIDENCE RATE</u>	as defined by OSHA, is the number of injuries and/or illnesses or lost workdays per 100 full-time employees.
<u>INFANT DEATH</u>	death occurring to live born individual of less than 1 year of age.
<u>INFANT MORTALITY RATE</u>	the number of infant deaths per 1,000 live births, usually expressed as an annual rate.
<u>LEGITIMATE BIRTH</u>	a birth to a married women whose husband fathered the infant.
<u>LIVE BIRTH</u>	a live birth is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration and pregnancy, which after such separation, breaths or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

MATERNAL DEATHS

those wherein the physician has designated a maternal condition as the underlying cause of death.

MATERNAL MORTALITY RATE

the number of maternal deaths per 10,000 live births, usually expressed as an annual rate.

MINOR CIVIL DIVISION

New Jersey Minor Civil Divisions are legally incorporated political subdivisions and are the local level of civil government. Cities, municipalities, townships, villages and town exhaust the area of the state all are exclusive (none overlaps another though may surround another).

MORTALITY

the number of deaths.

MOTOR VEHICLE

any mechanically or electrically powered device (except one moved by human power), not operating on rails, upon which or by which any person or property may be transported upon a land highway. The load on a motor vehicle or trailer attached to it, is considered part of the vehicle. Tractors and motorized machinery are included while self-propelled in transit or used for transportation. Also included are motor scooters, motorized bicycles and snowmobiles.

MOTOR VEHICLE ACCIDENT

any accident involving a motor vehicle in transport (in motion, in readiness for motion, or on roadway, but not parked in a designated parking area) that results in death, injury or property damage.

MOTOR VEHICLE TRAFFIC ACCIDENT

a motor vehicle accident which occurs on a trafficway -- a way or place, any part of which is open to the use of the public for purposes of vehicular traffic.

MOTOR VEHICLE NONTRAFFIC ACCIDENT

Any motor vehicle accident which occurs entirely in any place other than a trafficway.

NEONATAL

of, relating to, or affecting the newborn and especially the human infant during the first month of life.

NEONATAL DEATH

live born infant who dies before completing four weeks (28 days) of life.

NEONATAL MORTALITY RATE

as used in this text, the number of deaths of infants under 28 days of age per 1,000 live births, per year.

NIGHT

(motor vehicle accident) is the time interval between sunset and sunrise.

NONFATAL INJURY ACCIDENT

an accident in which at least one person is injured and no injury terminates fatally.

NONMOTOR VEHICLE

any vehicle other than a motor vehicle, except a scooter, wheelchair, roller skates, ice skates, skis, baby carriage, and similar means of transportation; persons using these latter means of transportation are considered pedestrians.

OCCURRENCE DATA

data allocated by place where event occurred, regardless of the person's place of residence (marriages, divorces).

OUTPATIENT ABORTION FACILITY

licensed health care facility other than a hospital in which abortion procedures are performed.

OUT-OF-WEDLOCK BIRTH

birth wherein there is no marital tie between mother and father.

PEDACYCLE

a vehicle propelled by human power and operated solely by pedals, excludes mopeds.

PEDESTRIAN

any person who is not in or upon a motor vehicle or non motor vehicle (see definition of motor vehicle) included as pedestrians are persons using a coaster wagon, child's tricycle, roller skates, etc. Excluded are persons boarding, alighting, jumping or falling from a motor vehicle in transport.

PERINATAL

of, relating to, or affecting the fetus and the newborn, especially the human infant during the first month of life.

PERINATAL MORTALITY RATE

number of deaths of infant less than 28 days of age (Neonatal Deaths), and registered fetal deaths per 1,000 live births plus registered fetal deaths.

PERMANENT DISABILITY

(synonymous with permanent impairment) includes any degree of permanent impairment of the body, such as amputations, permanent impairment of vision and other

permanently crippling nonfatal injury ranging from the permanent suffering of a joint or a finger amputation, to permanent, complete crippling.

PREMATURE BIRTHS

products of conception weighting less than five pounds, nine ounces (2,500 grams or less) at delivery or expulsion.

PROPERTY DAMAGE ACCIDENT

an accident which results in property damage, but in which no person is injured.

PROSTAGLANDIN

a class of drugs used to induce a second-trimester abortion; usually injected into the uterine cavity by a needle inserted through the abdominal wall or introduced as a vaginal suppository.

PUBLIC ACCIDENT

any accident other than motor-vehicle that occurs in the public use of any premises, includes deaths in recreation (swimming, hunting, etc.) transportation except motor-vehicle, public buildings, etc. and deaths from widespread natural disasters even though some may have happened on home premises. Excludes accidents to persons in the course of gainful employment.

RACE

(as relates to birth certificate) race for mother, father or as stated on the certificate. Race of child is determined from the race of the parents.

RACE-SPECIFIC MORTALITY RATE

number of deaths in a given race group per 100,000 estimated population in that ethnic group.

RATE

a rate measures the frequency of occurrences of some particular event. A rate is of the form: $\frac{x}{y} \times k$

- Where x = number of times an event has occurred during a specific interval of time.
- y = number of persons exposed to the risk of the event during the same interval.
- k = some round number (100; 1,000; 10,000; 100,000; etc.) or base, depending upon the relative magnitude of x and y.

RESIDENCE

usual place of residence of person to whom event occurred. For births and fetal deaths, residence is defined as the mother's place of residence.

RURAL

(for motor vehicle reporting) includes places of less than 5,000 inhabitants, except those classified as urban by the U.S. Census Bureau.

SALINE INSTILLATION

second-trimester method of induced abortion usually performed at or after 16 weeks of pregnancy by instilling a concentrated salt solution into the amniotic sac by a needle inserted through the abdominal wall.

SECOND AND THIRD TRIMESTERS

pregnancy of 13 or more weeks as determined by the history given by the patient, the physician's findings or clinical examination of the size of the uterus before the abortion, and/or the size of the fetus as examined after the abortion (NJAC 8:40-4.1).

SEX-SPECIFIC MORTALITY RATE

number of deaths of males/females per 100,000 estimated males/females in the population.

SHARP CURETTAGE

dilation of cervix and removal of the product of conception by a semi-sharp spoon-shaped instrument.

SUCTION CURETTAGE

dilation of cervix and removal of the products of conception by a vacuum method.

SUICIDE

the act or an instance of taking one's own life voluntarily and intentionally.

TEMPORARY TOTAL DISABILITY

an injury which does not result in death or permanent disability, but which renders the injured person unable to perform regular duties on one or more full calendar days after the day of the injury.

TRIMESTERS

1st - first 12 weeks of pregnancy
2nd - second 12 weeks of pregnancy
3rd - period after first 24 weeks of pregnancy

UNDERLYING CAUSE OF DEATH

that condition giving rise to the chain of morbid events leading to death, or the circumstances of the accident or violence that produced the fatal injury.

URBAN

(for motor vehicle reporting) includes places of 5,000 or more inhabitants, and the towns, townships and other areas classified as urban by the U.S. Census Bureau.

WORK HOURS

are the total number of hours worked by all employees. They are usually compiled for various levels, such as an establishment, a company or an industry. A work hour is the equivalent of one employee working one hour.

WORK INJURIES

(including occupational diseases) are those which arise out of and in the course of gainful employment regardless of where the accident occurs. Excluded are work injuries to domestic servants and injuries occurring in connection with farm chores which are classified as home injuries.

WORKERS

are all persons gainfully employed, including owners, managers, other paid employees, the self-employed, and unpaid family workers, but excluding domestic servants.

SECTION III

**CENTER FOR HEALTH STATISTICS
DIVISION OF RESEARCH, POLICY AND PLANNING
NEW JERSEY DEPARTMENT OF HEALTH**

**NEW JERSEY
STATE AND COUNTY POPULATION ESTIMATES
BY
AGE, SEX, AND RACE
JULY 1, 1984**

These estimates should only be used for statistical purposes as applied to health data.

NOTE: These age, sex, and race levels were developed using the Official State Estimates provisional for July 1, 1984 which were released by the Department of Labor, September, 1985. The age, sex, and race levels contained in this report are not official estimates and are intended for statistical use by health professionals in computation of morbidity and mortality rates by age, sex, and race characteristics and in projecting ranges of "need".

Center for Health Statistics
N.J. Department of Health
October, 1985

DATA AND ESTIMATING METHOD

The age, sex, and race estimates in this report were developed for Health Statistics Purposes Only. While these estimates are considered crude, they represent the only age, sex, and race data available for July 1, 1984. These estimates were generated, using as county controls, the Department of Labor's "Official State July 1, 1984 Population Estimates,"¹ which include values for total population by county, and residents aged 65 and over.

To generate the age, sex, and race proportionate shares for New Jersey and its 21 counties (except Cape May, Hunterdon, Sussex, and Warren) linear interpolation was performed between 1982 estimate values released by Richard Irwin at the U.S. Bureau of the Census and the 1990 Population Projections developed from the ODEA Economic - Demographic Model prepared by the New Jersey Department of Labor. These data were released to the Center for Health Statistics for internal use only and to be used to generate the estimates herewith presented. These 1990 population projections released to the NJ/DOH did not present age, sex, and race information for Cape May, Hunterdon, Sussex and Warren counties because of small values, especially for the nonwhite population. To generate values for Cape May, Hunterdon, Sussex, and Warren counties, the July 1, 1985 projections by the Department of Labor were used. Because these projections are not race specific, a proportionate shares technique was used to allocate race based on each county's racial composition reflected in Richard Irwin's 1982 county, age, race and sex estimates.

While the estimates herewith presented attempt to account for births, deaths, aging, and migration factors in the population through the use of linear interpolation between 1982 estimates and 1985 or 1990 projections (as described above) and statistical control to 1984 provisional county estimates, they are only very crude estimates. They are, however, all that are available in the absence of any hard indicators of actual population age distributions by race and sex that could be more ascertained through use of administrative records (i.e., medicare, school enrollment, driver's license, auto registration, taxation, etc.). These crude estimates were generated and are intended only for use by health professionals for statistical purposes such as computation of morbidity and mortality rates and health planning modeling of "need" for health care services by age, sex, and race at the county level.

Users should be aware that the 1984 base county population level used to generate these data may not agree to individual breakdowns, and that county values may not add to state values because of rounding and the different interpolation basis required for the four counties with the sparsest populations. It should also be noted that these estimates are not official and are only a guide as to the actual characteristics of the counties.

SUICIDES

1980-1984

**CENTER FOR HEALTH STATISTICS
NEW JERSEY DEPARTMENT OF HEALTH**

BACKGROUND

Durkheim (1951) was the first social researcher to do an in-depth study of social factors which affect risk of suicide. He observed that suicide rates were higher among Protestants than Catholics, higher among the divorced than among the married, and higher during periods of political lethargy than during crisis. Later Dublin (1963) pointed out that older white males, urban dwellers, and the divorced and widowed had markedly elevated risks of suicide. In Dublin's own words: "We have seen that certain environmental factors - economic conditions, city life, religious affiliations, social customs, and laws and traditions - influence the prevalence of suicide. It also differs markedly in various groups of the world's population with relatively high rates in some areas, low rates in others, and striking differences in the two sexes, in the several age periods, and in the principal races into which mankind is divided."

New Jersey had the lowest suicide rate of any state in the nation in 1980 according to the Centers for Disease Control Suicide Surveillance report issued March 1985: 7.4* suicide deaths per 100,000 population in New Jersey compared to the highest in Nevada (22.9 per 100,000) population. New Jersey's suicide rate has increased by 12.8% in the five year period 1980 to 1984 to a rate of 8.6 per 100,000 population in 1984.

A Youth Suicide Prevention Act (N.J.P.L. 1985, Chapter 195, also N.J.S.A. 30:9A-12) established suicide intervention programs in the schools and crisis intervention programs for adolescents and their families. Information on services available may be obtained from:

*New Jersey official statistics show a suicide rate of 7.8 per 100,000 population in 1980.

INTRODUCTION

Suicide is a serious public health problem, but less so in New Jersey than nationally. In 1980 suicide was the 13th ranking cause of death in New Jersey (among persons of all ages) and the 10th ranking cause of death nationally. In 1984 suicide ranked as the 12th leading cause of death in New Jersey and the 8th leading cause of death nationally. While suicide is a concern at every age (beyond 1 year) its rank as a leading cause of death is highest among New Jerseyans aged 15-24, where it is tied with homicide as the second leading cause of death. Suicide drops steadily as a leading cause of death from increasing ages to 17th place for persons above age 65 (Table 1) in New Jersey.

New Jersey's rate of suicides per 100,000 population has risen from 7.8 to 8.6 between 1980 and 1984, but New Jersey's suicide rate is far below that of the U.S.: 12.3 per 100,000 persons in 1984 (Figure 1 and Table 2).

White males consistently have the highest suicide rates of any race and sex category (Figure 2 and Table 3). Nonwhite males had the second highest rates followed by white females and nonwhite females. Rates have risen in all 4 race sex groups over the period from 1980 to 1984.

TRENDS BY AGE

Nationally, suicides at young ages were of such concern that a public health objective was formulated: "By 1990, the rate of suicide among people 15-24 should be below 11 per 100,000." New Jerseyans have been below the objective for each of the five years studies, but the rate rose from 7.9 to 9.5 per 100,000 between 1983 and 1984 (Table 4).

Suicide rates tended to increase with age (Figure 3 and Table 4). Between 1983 and 1984 there was an increase in suicide rates for each age group, except those over 65. In 1984, New Jersey's suicide rate for persons aged 65 and over was 11.9 per 100,000 population compared to 19.4 per 100,000 population nationally. According to Grollman (1971), the elderly commit suicide the most of any age group, but attempt suicide the least. According to Busse and Pfeiffer (1969) the impact of retirement, especially for men, of physical decline, or somatic illness are among the speculated reasons why older people take their lives. Loss of a mate is well known to increase the risk of suicide (Parkes, 1969; MacMahon and Pugh, 1965); and cancer diagnosis may as much as double the risk (Marshall, J.R., 1983).

Of the 112 geriatric (65 and above) suicides in New Jersey in 1984, 73 (or 65.2%) were white males; methods of lethality for white males aged 65 and over tended to be firearms (30 or 41.1%) and hanging (24 cases or 32.9%).

Adolescent suicides (Table 5) were the highest in New Jersey in 1984 with 47 cases compared to 36 in 1983. The median age among teenage suicides showed fluctuations over the 5 years studied ranging from 17.6 years in 1983 to 16.9 years in 1984. In New Jersey in 1984 the suicide rates for persons aged 1-14 and aged 15-24 were .4 and 9.5 per 100,000 persons (compared to national rates of .6 and 12.2 per 100,000 respectively).

Median ages for persons who died of suicide by race and sex over the five years studies are shown in Table 6. Males tended to commit suicide at younger ages than females; nonwhites tended to show less of an age differential based on sex than whites and tended to commit suicide at younger ages than whites of the same sex. A complete age distribution by sex and race is shown in Table 7 for 1984 cases.

METHODS OF LETHALITY

Method of suicide over time, 1980 to 1984, was shown in Table 8. Most frequently employed methods were firearms and hanging, strangulation, and suffocation. Among poisonings (22.2% of all suicides in 1984) solid or liquid substances increased in use over the period 1980 and 1984 (from 8.7% to 11.7%) while gas poisonings decreased (from 13.4% to 10.5%).

Variations in method by race and sex for suicides committed in 1984 were shown on Table 9. Firearms and hangings were the most frequent methods of injury for white males. Hangings and firearms were the most frequent for nonwhite males. For females of both racial groups hangings were most frequent, followed by solid or liquid poisonings.

Methods also vary with age with firearms more frequently used among adolescents (44.7% of teenage suicides compared to 34.6% of all suicides in 1984). Hanging (ICD-9 code 953.0) was also more frequent among teenagers (31.9% of teenage suicides occurred by this method of injury in 1984); hangings represented 26.2% of all suicides in 1984.

*1 white person of unknown sex, died of drowning.

SEASONALITY

Suicides were more likely to occur in February, March, April (for females, not males), May and June than during other times of the year. Seasonal trends are shown in Table 10. A ratio of seasonality was used to compare the actual number of suicides each month to the expected number (adjusted for the length of the month). Seasonal variation differed between sexes (Figure 4) with July and December being infrequent times for suicides among females and November being a more frequent time for females than males; seasonal variation was much greater for females than males.

Figure 4

Title: Seasonality of Suicides, By Sex,
for New Jersey Residents: 1980 to 1984

RESIDENCE

The resident suicides by age and sex are shown for New Jersey counties and principal municipalities in 1984 on Table 11. Counties with the highest suicide rates were Atlantic (13.4 per 100,000 population and Camden (13.2 per 100,000 population) compared to Union (5.5 per 100,000 population and Essex (6.4 per 100,000 population) which were the lowest county rates (Table 12). Rates of change between 1984 and 1980 were computed, but care should be taken in interpretation because of the small number of cases at the municipal level.

*Undefined rate of change because there were no cases in 1980.

METHODOLOGICAL ISSUES

Suicides in this report are those deaths identified as having cause-of-death codes E950-E959 from the International Classification of Diseases, ninth revision (ICD-9).

Suicide statistics based on death certificates probably understate the true number of suicides for several reasons (as stated by the CDC Violence Epidemiology Branch):

- 1) Inadequate information on which to make a determination of suicide as the cause of death.

Without an explicit communication by the victim that the death was self-inflicted, the death might be erroneously ruled as homicide or an accident or will be ruled as undetermined. In other circumstances, there may be either conscious or unconscious attempts to obscure information necessary to make the determination of suicide, as in the case of family deliberately withholding or unconsciously denying information to avoid stigmatizing themselves or the victims.

- 2) Certifier bias or error.

The certifier may be influenced in recording an accurate certification of suicide because of pressures brought to bear by family or friends of the suicide victim. Also, error in judgment may occur on the part of the certifier because of inadequate criteria or standards for making a determination of death by suicide given a particular set of circumstances. That is, based on the same set of information, two certifiers may rule differently as to whether the death should or should not be determined to be suicide.

- 3) No death certificate filed on the victim.

Some suicide deaths might not be recorded if the bodies are never found. This bias may be more significant for specific methods of suicide, e.g., drowning after jumping from a high bridge.

If suicides are misclassified on death certificates, these deaths are most likely to be reported under accidental deaths as pointed out by Douglas in 1967. From Holdings and Barraclough's comparative studies, the underestimate of the true suicide rate reflected by official statistics may be as much as 22%.
