DEPARTMENT OF HEALTH

CN 360. TRENTON, N.J. 08625-0360

MOLLY JOEL COYE, M.D., M.P.H.
COMMISSIONER

September 1, 1988

Dear Colleague:

I am pleased to announce the availability of our twenty-seventh annual Health Statistics report. This year's report reviews suicides from 1980 to 1986. The section on Communicable Diseases depicts the predicted upswing in Acquired Immunodeficiency Syndrome (AIDS) cases and deaths. Also, population estimates by age, race, and sex are updated to July 1, 1986. As always, there is a wide variety of statistical breakdowns provided for births, deaths, marriages, divorces, fertility, abortions, and hospitalizations.

The New Jersey State Department of Health is proud to operate the oldest health statistics reporting system in the United States, which began operation 111 years ago. Our purpose remains to "...take cognizance of the interest of health and life among the citizens of their state" by providing this comprehensive accounting of our vital statistics. I trust you will find the contents helpful.

Sincerely,

A handwritten signature in cursive script that reads "Molly Joel Coye".

Molly Joel Coye, M.D., M.P.H.
State Commissioner of Health

NEW JERSEY HEALTH STATISTICS 1986

INTRODUCTION

Health Statistics is comprised of individual reports compiled by the Center for Health Statistics from the State's vital statistics data base. The scope and coverage of Health Statistics currently includes highlights, historical perspective, natality, mortality, marriages, divorces, communicable diseases, accidents, fertility, abortions, hospitalizations, population, vital statistics gross summary and two special reports covering Suicides 1980-1986 and 1986 County Population by Age, Sex and Race. A section of technical notes is included that explains the statistical methods used and data limitations; a list of definitions and a description of rates, ratios, proportions, and indices are also covered.

State and county statistics are presented along with selected municipality (MCD) data, when appropriate. The Vital Statistics Gross Summary presents municipality data for population, births, deaths and marriages. Additional vital statistics at the MCD level are available for inspection and use in the Trenton central office of the Department. Copies of specific MCD information have been supplied to county and local Health Officers.

Births, deaths, marriages, and fetal deaths occurring in 1986 are statistics presented in this Volume. They were obtained from certificates filed with the State Registrar prior to July 1, 1987. Through a reciprocal arrangement between states, copies of birth, death, and fetal death certificates involving out-of-state occurrences are interchanged. Thus, the resident birth, death and fetal death rates shown in the report include all events involving residents of the State of New Jersey, irrespective of place of occurrence. Marriage statistics, however, are treated differently. A tabulation is made of all marriages occurring within the State, irrespective of the residence of either party. Copies of marriage certificates are not interchanged between states as such a procedure would prove impractical (see Technical Notes).

The Tuberculosis Control, Sexually Transmitted Disease, and Communicable Disease Control programs are responsible, by law, for maintaining confidential files on "reportable diseases." Statistics maintained are tabulated by the Center for Health Statistics annually and are included in the report in order to allow the user to develop a more complete profile of the health of State residents.

The newly formed AIDS Division has developed a database file which will eventually contain all identified AIDS cases within the State. Comparable statistics on the number of reported cases within New Jersey, or by state of residence, are presented through the year 1986. All requests for statistics related to AIDS should be directed to the New Jersey AIDS program.

Data relating to hospitalizations were obtained from medical discharge abstract summaries. The Uniform Bill Patient Summary data are submitted to the Department for use in the hospital rate-setting program. Other discharges from hospitals not participating in the rate-setting program are submitted directly to the Center for Health Statistics. Discharge Abstracts are received from all patients at time of discharge, regardless of the patient's disposition or place of residency.

Accident reporting is derived from the death certificates and is presented in two parts. The first comprises aggregated accidental deaths relating only to New Jersey residents; the second presents a detailed statistical listing of all deaths occurring within the State regardless of place of residence, by category and type.

The Office of Demographic and Economic Analysis, Department of Labor, is assigned the responsibility by the Governor of the State to provide Official State Annual Estimates of Population for all 567 municipalities and 21 counties. These estimates are periodically revised to reflect the latest information available with respect to births, deaths and migration. The revised July 1, 1985 estimates, released in September 1987, were used in developing the vital statistics rates shown in this report. All rates for prior years were recalculated based on the Revised Population Estimates. Age, sex, and race specific estimates for 1986 were developed by the Center for Health Statistics, based on the "Proportionate Share Techniques" using the 1980 census data controlled to the July 1, 1985 revised estimates. The age, sex, and race data presented in this report are considered as crude estimates and should only be used for statistical purposes. The population for 1986 was assumed to have the same age, sex, and race distribution as existed in the 1980 Census, adjusted by subsequent births, deaths and migration patterns.

Back issues of Health Statistics for 1979 through 1985 are available, as long as supplies last. They can be obtained by writing to the Center for Health Statistics. Vital statistics data and reports from 1977 through 1986 are maintained for reference purposes by the N.J. State Library and the Center for Health Statistics. Inquiries regarding the contents of this report should be addressed to:

NJ Department of Health

How to Use This Report

Overview

The purpose of the annual New Jersey Health Statistics Report is to provide a comprehensive summary of those vital statistics compiled and maintained by the New Jersey Department of Health. This report is the primary vital statistics reference document for 1986 data. However, only data most often requested are included in this document. Additional information is available from the Center for Health Statistics, New Jersey Department of Health. The user of this report is advised that the data contained herein were correct for the calendar year 1986 up until June 1, 1987. They are subject to change if corrections or additional information becomes available.

Page Numbering System

This report is divided into four sections, I-IV and 15 subsections, A-N. For quick identification and easy access, each subsection of the report has been given a letter. A "TAB" page numbering system has also been used, so that the user can rapidly locate individual subject areas. All tables within Section I have been indexed and included in Section IV--Index.

Additions and Revisions

The report has been developed in "loose-leaf" format to permit additions and revisions. All holders of the report who are registered with the Center for Health Statistics will automatically receive copies of revisions and/or additions when released. If a three-ring binder has not been supplied, the holder is advised to place the document in a three-ring binder. All pages have been "three-hole" punched. Sections can be located by determining the TAB page in the Table of Contents, then flipping through the document to find the appropriate location. To register or report change of address, please forward the following information to the Center for Health Statistics:

Trenton, New Jersey 08625

Highlights 1986

POPULATION

New Jersey reached a 1980 population total of 7,364,823 persons ranking it 9th in the nation. With an average of 983.0 persons per square mile it continued to retain its position as the most densely populated of the states. The 1980 Census indicated that New Jersey's median age is 32.2, slightly higher than the U.S. level of 30.1. The percentage of population 65 and older increased between 1970 and 1980 at a rate of 2½ times the national figure--a rate of growth exceeded in only four states. Projections indicate a continued increase in the percentage of the older population in the State. The July 1, 1986 total population estimate of 7,620,000 indicated a slight increase of 58,000 for the State as a whole since the 1980 census. The 1985 revised estimate is 7,562,000.

INCOME

New Jersey's per capita personal income of \$18,866 for 1986 was 28.9% higher than the national level of \$14,636 and ranked New Jersey 3th in the country. New Jersey ranked third in 1985, but was superseded for first place by Connecticut this year. Nine percent of New Jersey families are below poverty level placing New Jersey 44th among the states. Per capita, disposable personal income has progressively increased since the 1980 Census, and by 1984 reached the level of \$13,179 (compared to \$10,951 for the U.S.).

MARRIAGE/DIVORCE

The State's annual marriage rate has fluctuated continually since 1946 when it reached a high of 14.2. In the mid 1980s, it moved upward again to reach its highest levels since the WW-II level. The divorce rate increased in the late 1970s and early 1980s, declining slightly in the past three years. For every 100 marriages performed in New Jersey in 1986, 45.1 divorces were granted, a ratio of 2 to 1.

ABORTION

A total of 33,376 New Jersey resident women obtained legal induced abortions from licensed facilities in 1986, a 9.9% increase since 1985. Of those obtaining abortions 24.8% were under 20 years of age, and 55.9% were in the 20-29 year group. Over three-fourths (77.0%) were unmarried, 50.1% had no living children, while 53.6% had no previous abortions, and 53.3% obtained the abortion prior to the 9th week of gestation.

BIRTHS

New Jersey experienced an increasing birth rate between 1977 and 1986 but currently ranks 44th among the states in birth rates per 1,000 people. The national rate for 1986 was 15.5. The New Jersey rate was 14.2, 8.4% below the national level. Resident births in the State were recorded at 108,444. The 1986 level represented a 3.0 percent increase over 1985.

...Age of Mother

Births increased in New Jersey over the 1985 level. However, women in their teens showed a decrease of 23 births or 0.2%, while those aged 20-34 showed an increase of 2,282 births or 2.7%. Women 35 years and older showed an increase of 86 births or 9.6%.

...Live Birth Order

Forty-four percent of births to New Jersey residents were first order births. The general long-term trend has been toward a greater percentage of higher order births in the State.

...Births to Unwed Mothers

Of all live births in New Jersey during 1986 22.7% were to unwed mothers. The ratio of births to unwed mothers is highest for teenagers. For mothers in the age group of 20 years and older, the ratio in New Jersey exceeds the national level.

...Low Birth
Weight

In 1986 the incidence of low birth weight babies in New Jersey declined 0.1% from the 1985 level of 6.8%. The incidence in the State remains slightly higher than nationally, and is highest for younger and older women and lowest for women between the ages of 25 to 34.

...Multiple
Births

There were 2,159 live births in multiple deliveries. Of these, 2,094 (97.0%) were twins, and 65 (3.0%) were three or more infants.

MORTALITY

With an older population age structure than the U.S., New Jersey's crude death rate exceeds the national figures; age adjustment of the rates reveals a mortality closer to that experienced nationally. For 1986, the New Jersey crude mortality rate per 1,000 population was 9.4 (U.S. rate 8.7). Total deaths in New Jersey registered 71,299, an increase of 644 over the 1985 level of 70,655.

...Life Expectancy

The expectation of life at birth reached a new U.S. high in 1986--an estimated 74.9 years for the total population. Life expectancy at birth for New Jersey residents was 74.0 years in 1980. New Jersey was the 23rd State when ranked on this indicator. Life expectancy for New Jersey females is 77.4, while males have an expectancy of 70.5 years (based on 1980 information).

...Leading Causes

In 1986, heart disease, cancer, cerebrovascular diseases, and pneumonia and influenza continue to be the leading causes of death in New Jersey. Mortality from heart disease, cancer and pneumonia and influenza is higher in New Jersey than nationally, but the mortality rate from cerebrovascular diseases of 57.4 is 6.4% lower than the national rate of 61.3. Overall, mortality in the State decreased in 1986 for diseases of the heart, malignant neoplasms, cerebrovascular diseases, chronic liver disease and cirrhosis, suicide, and atherosclerosis, while increasing for accidents, and influenza/pneumonia, septicemia, bronchitis, emphysema, asthma, and homicide. Accidents were the leading cause of death for those between the ages of 1 to 24. Homicide and suicide were the next two leading causes of death for those between 15 to 24 years of age.

INFANT MORTALITY

Infant deaths decreased by 58 to 1,055 in 1986, and the 1986 infant mortality rate decreased to 9.7 per 1,000 births from the 1985 rate of 10.6. Both the neonatal death rate and the infant death rate have been on a downward trend since the Department started collecting statistics in 1879.

MATERNAL MORTALITY

New Jersey's maternal mortality rate has been consistently lower than the U.S. maternal mortality rate. Only 3 maternal deaths occurred in 1985, the lowest number to date. However, in 1986, there were 9 maternal deaths in the state.

FETAL MORTALITY

A total of 1,166 resident fetal deaths were reported in 1986. The 1986 level was the highest since 1977. Also, the fetal death rate increased slightly to 10.8 (up from 10.6 in 1985). Nevertheless, over the past 50 years the State's fetal death rate has declined.

COMMUNICABLE DISEASES:

...Gonorrhea

The total number of reported cases in the State decreased slightly from the 1985 level of 19,751 to 19,612 in 1986 (a drop of 139 cases or 0.7%).

...Syphilis

New Jersey's case rate for all stages of syphilis decreased from 30.2 cases per 100,000 population in 1985 to 26.2 in 1986.

...Tuberculosis

The State's incidence for tuberculosis increased from 839 cases in 1985 to 948 in 1986 (or 13.0%). Clinically active cases increased during the same period from 545 to 724 cases (or 32.8%).

...Other

In 1986, 4 cases of rubella were reported, a decline from 11 cases reported in 1985. Hepatitis Type A decreased 3.5% from 397 to 383 cases, while Type B decreased by 22.6%. After a minor outbreak of measles in 1981 (61 cases), the number reported dropped to 3 in 1983. In 1986 measles cases increased dramatically to 881 cases.

...AIDS

The diagnosed number of AIDS cases in New Jersey has increased from 687 cases in 1985 to 1,079 in 1986. Likewise, the number of AIDS related deaths increased from 363 in 1985 to 653 in 1986. Rates per 100,000 population for diagnosed cases climbed from 9.1 to 14.2 between 1985 and 1986; rates for deaths jumped from 4.8 to 8.6 during the same time period.

ACCIDENTS

In 1986 total accidental deaths by occurrence in New Jersey increased slightly over the 1985 level from 2,294 to 2,353 deaths. Motor vehicle accidents remained the major cause accounting for almost one-half of all accidental deaths in each of the years. Motor vehicle deaths increased from 1985 with pedestrians accounting for almost one-fourth of all motor vehicle deaths. Falls and fires accounted for over 50% of the "In-home" category. Drownings and falls accounted for almost forty percent of the nonmotor vehicle deaths that occurred outside the home. The 1986 ranking of residents' deaths by class of accident in any location or specific setting was: motor vehicle, falls, fires, poisonings, and drownings.

Historical Perspective 1986

INTRODUCTION

The historical perspective presented in this report includes an overview of socio-demographic trends and mortality statistics for the United States and New Jersey. Trends in births, deaths, marriages, divorces, fertility, and average length of life are emphasized. Also changes in the incidence of selected communicable diseases are summarized.

STATISTICAL OVERVIEW

U.S. TRENDS

The total United States population including Armed Forces overseas reached 241.0 million on July 1, 1986, an increase of 0.2 percent from the previous year. The preponderance of population growth has been in the South and West with these two regions accounting for 91.0 percent of the nation's growth between April 1, 1980 and July 1, 1986. Recent projections indicate that the population will increase to 249.7 million by 1990 and to 268.0 million by 2000. These increases are based on the assumption that United States couples will have an average of two children.

The rate of population growth has slowed substantially since the 1950's. The decrease in the annual number of births from 4.3 million in the late 1950's to 3.7 million in 1985 and 1986 has more than offset the increase in life expectancy from 68.2 years in 1950 to 74.9 years in 1986. If the growth rate experienced in the 1970s continues, the population will double in size in about 85 years. In other industrialized countries with slower growth rates than the United States, such as the German Federal Republic, England and Wales, it will take as many as 347 years for the population to double. In the lesser developed countries with higher rates of growth, such as Mexico, the population will double in about 17 years.

By the end of the century the number of people 65 years of age and over in the United States is projected to increase by about 5 million from 12.9 percent of the population in 1986 to 13.1 percent by 2000. Since the elderly are less healthy and utilize more health services than younger people, there will probably be an increase in demand for health and social services.

Birth rates in general have steadily decreased since the late 1950's with women having their first child at a later age than in the past. From 1972 to 1976, rates of having the first child increased for women in age groups 25-29 and 30-34 but decreased for women 20-24 years of age. Birth rates for young teenagers between 15-17 did not begin to drop until the early 1970s, unlike the rates for older teenagers, 18-19, which declined similarly to the rates for women 20-24 years of age.

The national crude death rate has remained steady since 1975, ranging from 8.5 per 1,000 population to 8.8. A comparison of the crude death rate between the United States and New Jersey shows that the New Jersey rate of 935.7 per 100,000 is higher than the United States rate of 870.8. This difference is presumably related to a higher concentration of older age groups with higher death rates in New Jersey.

Between 1975 and 1986 the United States infant mortality rate per 1,000 live births dropped 35 percent from 16.1 to 10.4. The decline in actual infant deaths was slightly over 20 percent. The infant mortality rate for New Jersey was 6.7 percent lower than the United States rate of 10.6 in 1986. Infant mortality rates in New Jersey have declined similarly to those for the United States during the past 10 years.

Average length of life in the United States since 1950 increased from 68.2 years to 74.9 years, a 9.8 percent gain. The increase in average life span was greater for females; their average length of life increased from 71.1 years in 1950 to 78.3 years in 1986 or 10.1%. The average length of life for males over the same thirty-five year period rose from 65.6 to 71.3--a gain of 8.7%. The average length of life for Blacks has been increasing faster than for Whites since data became available in 1970. However, their life expectancy is still lower, being 65.5 for males and 73.6 for females.

NEW JERSEY TRENDS

New Jersey is the most densely populated state in the nation (1020.4 persons per square mile as of July 1, 1986) and was the first state to pass a thousand persons per square mile. Future population increases are expected to be lower than for the nation as a whole. However, the annual growth rate of about 0.6% during this decade is higher than the 0.3% per annum growth that took place over the 1970-80 period. The New Jersey Department of Labor recently projected that by the year 2000 the State's population would reach the 8.5 million mark; 9.2 million is anticipated by July 1, 2020.

The population growth that is predicted should result from an increase in the number of births and projected in-migration from bordering states. The projected increase in births is based on the relatively large numbers of women in the childbearing ages between 15-44 years of age. Based on current trends, strong employment growth is indicated in several counties that should attract workers from bordering states.

Looking back, New Jersey's population grew much faster than the nation's during the fifties and the sixties, despite lower birth rates and higher death rates. The rapid growth in the State's population was attributed to a large net in-migration that took place mostly from the neighboring states of New York and Pennsylvania. In the 1970s, however, New Jersey registered an almost stationary 2.7 percent population growth as compared to the 11.4 percent average rate for the United States. The reversal that took place during the seventies of the previous trend was almost entirely because of a net out-migration.

The State's population growth was in suburbia and was concentrated more in the northeast and southwest counties than in the rural or shore areas. The urban areas, in contrast, experienced a population decline from 1970 to 1980 as the shrinking of the State's industrial base had its impact. Still, nine out of ten of the State's residents continue to live in the major urban centers of the State.

The racial composition, age distribution, and other population characteristics did not change significantly in New Jersey between 1970 and 1980. The characteristics for 1980 are similar to those of the United States. However, two major differences in the composition have been observed: (a) the State's minority population is growing more rapidly than in the nation as a whole, due primarily to the in-migration of Hispanics; and (b) both the marriage and divorce rates remain noticeably below the national averages.

Over the years the trends in birth rates have paralleled those of the nation as a whole. While birth rates are higher nationally than in New Jersey, both rates declined from 1947 to the mid-1970s. In 1977 the birth rates began to increase in New Jersey and nationally, although slowly. The gap between the New Jersey and national birth rates widened between 1979-1982 with slower annual increases in New Jersey than nationally. Since 1983 the gap in birth rates has narrowed with higher increases in New Jersey.

The fertility rate, or ratio of live births per 1,000 women aged 15-44, is another indicator of actual birth trends. The fertility rate for New Jersey in 1970 was 81.2 compared to 82.6 births per 1,000 women for the nation. With the downward trend in population increases, out-migration and a lower birth rate, the fertility rate has been affected. By 1975 the fertility rate for New Jersey had dropped to 56.6, which was below the 65.8 rate for the United States. In the 1980s, the New Jersey fertility rate began to stabilize. It was 57 live births per 1,000 women in 1980. In 1986 the fertility rate was 60.4. During the same time period, 1980 to 1986, the fertility rate in the United States dropped from 68.4 to 64.9.

Mortality trends present a different picture from birth trends. In 1960 the State's mortality rate per 1,000 population was less than the national rate. In 1967 an increase in mortality started nationally which kept the New Jersey rate below that of the nation's. While the difference was not great, the rate remained below the national level until 1974, when New Jersey's crude mortality rate exceeded that of the United States. A higher crude mortality rate in New Jersey has continued since that time, producing a widening of the gap. Part of the reason New Jersey's rate is increasing more rapidly is the higher proportion of persons aged 65 and above in New Jersey. Persons in this age group comprised 12.9 percent of New Jersey's population in 1986, whereas 12 percent of the United States population fell into this age group.

Perinatal mortality is a composite statistic used to measure the critical period of human development just prior to birth and shortly thereafter. As presented in this report, perinatal mortality includes fetal deaths plus neonatal deaths of infants under 28 days of age. Since 1947 when New Jersey began computing perinatal mortality rates, the rate has decreased by 61 percent. It dropped from 41.4 to 16.0 deaths per 1,000 live births plus fetal deaths from 1947 to 1983. After a 10.0 percent upturn in 1985 raised the perinatal mortality rate to 17.6, the rate decreased to 17.1 in 1986. Over the last twenty-five years maternal deaths also have declined dramatically. In 1985 the lowest maternal death rate to date was recorded at 0.1 per 10,000 live births. However, a tripling of the number of maternal deaths (9) raised the rate to 0.2 in 1986.

Rates of homicide and suicide have changed dramatically since 1940, but in different directions. Homicide rates rose sharply in New Jersey from 1.7 per 100,000 population in 1940 to a high of 7.5 in 1981. The rate in 1985 and 1986 was 6.0, a decline of 20 percent since 1981. On the other hand, suicides decreased from 15.9 per 100,000 in 1940 to a low of 6.8 in 1970. Since then, the suicide rate has fluctuated between 6.8 and 8.9. The rate for 1986 was 8.7.

Tuberculosis cases and deaths are much less frequent now than in 1940 when almost 90 people out of 100,000 suffered from TB and 44% died. Corresponding rates of cases and deaths in 1986 were 12.4 and 1.0 per 100,000 population. However, the steady decline in cases and deaths may have bottomed in 1985.

Changes in the rates of syphilis and gonorrhea have been marked over the years. As syphilis is controlled, gonorrhea seems to spread. The rate for syphilis dropped from 247.1 in 1940 to a low of 24.7 in 1978. The rate for gonorrhea, on the other hand, rose from 73.6 cases per 100,000 in 1940 to a high of 310.5 in 1981. The incidence rates for primary and secondary cases of syphilis in New Jersey decreased from 10.0 per 100,000 in 1985 to 8.8 per 100,000 in 1986, 24.7 percent lower than the rate for the nation of 11.7. The gonorrhea incidence rate of 254.4 per 100,000 in 1986 was the lowest it has been since 1977, and it is far below the national rate of 376.4.

New Jersey's ranking of causes of death is the same as the nation's with the leading causes being heart diseases, malignancies, cerebrovascular diseases and accidents, all of which account for 71.7 percent of the deaths in New Jersey. While New Jersey's crude death rates for heart diseases and malignancies are higher than those for the nation, the reverse is true for cerebrovascular diseases and accidental deaths. Trends in death rates between 1970 and 1986 for the principal causes of death are presented in Table 8. While the rate for diabetes has dropped from 36.5 per 100,000 population in 1940 to 19.1 in 1986, the rate for heart diseases climbed, then returned to just above the 1940 rate of 358.9. Rates of death also are declining for cerebrovascular diseases. Rates of death are rising for malignant neoplasms and septicemia.

Natality 1986

INTRODUCTION

This Natalty report covers births to New Jersey residents for the calendar year 1986. Similar reports on deaths, marriages, abortions, and communicable diseases follow.

Statistics provided herein are summarized from reported birth certificate items filed with the New Jersey State Registrar. In New Jersey legislation requires that the attending physician, midwife, or person acting as midwife file a Certificate of Birth within five days of birth with the Local Registrar. Births to New Jersey residents that occurred during the calendar year in other states are recorded in the state of occurrence. All certificates are forwarded to the New Jersey State Registrar who maintains these records. Individual identifiers are removed prior to tabulation of data for statistical purposes.

STATISTICAL OVERVIEW

Number of Births

The trend in New Jersey's birth rate has paralleled closely that of the United States, although the state's rates have been consistently lower than those of the nation. In 1986, there were 108,444 resident births in New Jersey, the highest annual total since 1972. Births increased by 3.0 percent from the 1985 level of 105,329. Nationally, the number of births for 1986 reached 3,731,000. This provisional estimate reported by the National Center for Health Statistics indicates a decrease of 0.5 percent for the same period. In 1986 83,504 births in New Jersey were reported as white, 22,642 as nonwhite and 2,298 of unknown race. White births represented 77.0 percent of total births, while nonwhite births comprised 20.1 percent. White births increased 3.3 percent from the previous year; nonwhite births increased 2.3 percent.

Of the total births in the State, 1.9% or 2,094 were twins and 65 (0.1%) were triplets or even greater multiples. Single births were 97.9% of all births.

The ratio of male to female births in New Jersey for 1986 was 1,050 male to every 1,000 female births. This male/female ratio was down slightly from the 1985 level of 1,055. Between 1985 and 1986, the male/female ratio for white live births decreased slightly from 1,058 to 1,056 while nonwhites decreased from 1,053 to 1,032 (2.01%).

Birth Rate

During 1986 the birth rate in New Jersey rose 0.3 to 14.2 live births per 1,000 population. The birth rate is a measure of population increase. Once again, Camden County recorded the highest birth rate (16.5) and Bergen County the lowest (11.3). Other counties with rates above the state rate of 14.2 were: Passaic (16.1), Atlantic (16.0), Sussex (15.8), Cumberland (15.7), Hudson (15.5), and Essex, Gloucester and Warren with 15.2 percent each.

Fertility Rate

The most significant demographic factors associated with rising birth rates are the increase in the number of women aged 15-44 years and an increase in the fertility rate. The measure of the rate of childbearing in New Jersey increased slightly from last year's level of 59.2 to 60.4 in 1986. The fertility rate has fluctuated moderately since 1980 when the fertility rate was 57.4. While the fertility rate may have leveled off, one cannot lose sight of the fact that a downward trend has occurred in New Jersey over the past two decades. Since the early 1970s, the overall fertility rate has dropped by twenty-five percent.

Out-of-Wedlock Births

The incidence of out-of-wedlock births in 1986 was one of every 3.4 births. The level of births for which illegitimate status is reported appears to have stabilized for the last six years. For white women, the percentage of total births classified as illegitimate increased 0.9 of a point, while for black women an increase of 1.1 points was observed. Legitimate births to white mothers were 86.0 percent, down nearly 1 percent from 1985; for black mothers legitimate births were 36.2 percent in 1986, down from 37.3 percent in 1985. The percentages of illegitimate births attributed to whites versus nonwhites has remained about the same, 47.4% and 51.8% respectively, with the balance of 0.8% attributed to unknown groups.

Women aged 19 years old and younger gave birth to 32.3 percent of the children born out of wedlock. Seventy-eight percent of all births among women in this age group were illegitimate. In the 20-24 year old maternal age group, the illegitimate rate increased by 8.3 percent over 1985 to a level of 36.6 percent. For mothers 25 years of age and older the illegitimate rate was 10.5 percent. The 25-34 age group recorded 10.8 percent, an increase over 1985 of 0.7 percent.

NEWBORN HEALTH

Birthweight

The median weight group for newborns in New Jersey ranges between 6 lbs. 10 ozs. and 7 lbs. 11 ozs. Of total newborns during 1986, 36.4 percent were between 6 lbs. 10 oz. and 7 lbs. 11 oz. Almost two-thirds, 64.9 percent of the newborns, weighed between 6 lbs. 10 ozs. and 8 lbs. 13 ozs. The number of newborns in the median weight group has remained the same during the last decade. However, the percentage of newborns declined slightly.

The low birthweight group of newborns weigh 5 lbs. 8 ozs. (2,500 grams) or less. Of all New Jersey resident births for which weight was reported in 1986, 6.7 percent were recorded as low birthweight babies. White births weighing less than 5 lbs. 8 ozs. numbered 4,482 or 5.4 percent of all white births. Low birthweight, nonwhite births numbered 2,739 or 12.1 percent of all nonwhite births.

Statistics indicate that births to young mothers under 20 years of age are more likely to be premature with a low birthweight. A total of 1,096 or 10.7 percent of births to teenage mothers in 1986 were immature. Among nonwhite teenage mothers the percent of low birthweights was higher than for white teenage mothers. Underweight births to nonwhite teenage mothers represented 13.0 percent or 612 cases, compared to 8.9 percent or 481 cases for births to white teenage mothers.

Previous Pregnancy Terminations

The number of previous pregnancy terminations that a woman has had affects the incidence of low birthweight outcomes for subsequent pregnancies. In 1986 the incidence of low birthweight births to women with no previous pregnancy terminations was 6.4 percent. The percentage of immature births increased, however, with the number of previous terminations, as women with more than three previous terminations bore 14.2 percent low birthweight babies, an increase of 15.4 percent over 1985.

Prenatal Care

There is a positive relationship between birthweight and prenatal care. Low birthweight infants are born less frequently to women who begin prenatal care in the first trimester of pregnancy. The rate among this group was 6.0 percent, a decrease from the 6.2 percent observed in 1985. The percentage of immature births among mothers starting care during the second trimester of pregnancy was 8.4 percent, a drop of 0.2 from the 1985 percentage. Among those beginning care in the third trimester, the ratio was 8.4 percent, which was the same as last year's. Those receiving no prenatal care gave birth to low birthweight infants in 26.4 percent of the cases, up by almost one-third from the 1985 rate of 19.9 percent.

Apgar Score

The APGAR score is a composite measure used to evaluate the newborn infant's general condition. APGAR scores are given to newborns at one and five minutes after birth. Heart rate, respiratory effort, color, muscle tone, and reflexes are checked and evaluated. Each of these factors receives a score of 0, 1, or 2 and the sum of the five values is the overall score. A score of 10 is optimum. Newborns with scores less than 7 are considered distressed and are observed more closely for physical problems during the first days of life. There is a significant relationship between APGAR score and birthweight, neonatal mortality, and neurological morbidity.

Twenty-three percent of all newborns in 1986 received five-minute APGAR scores of 10. Of total births, 93.7 percent were in the 7-10 APGAR score range. Low APGAR scores for newborns of nonwhite mothers were more frequent than for newborns of white mothers. Among nonwhite births, 2.3 percent had scores less than 7. Only 1.0 percent of white births were in this low score range. Across age groups low APGAR score births were at the highest rate for mothers aged 14 years old and younger (4.4%). Low APGAR scores represented 2.0 percent of births to mothers under age 20. The percentage of newborns with low scores was 1.5 percent for mothers aged 20-44.

Low APGAR score births occurred less frequently to mothers who received prenatal care. Of births among women receiving prenatal care, 1.2 percent were in the 0 to 6 score range. Among mothers receiving no prenatal care, 6.2 percent of births were below 7.

MATERNAL CHARACTERISTICS

Age

The median age group for new mothers in 1986 was 25-29 years. Approximately one-quarter (22.5%) of all births were to women in this age group. Births to teenage mothers, 19 years and younger, accounted for 9.4 percent of the total, slightly lower than the 9.7 percent in 1985. Teenage deliveries were highest as a percentage of total births in Cumberland (19.9%), Essex (15.5%), Passaic (13.4%), and Mercer (13.1%) counties. Bergen had the lowest (2.6%) proportion of births to teenage mothers, followed by Morris (3.1%) and Somerset (3.5%). Women 35 years of age and older gave birth to 9.1 percent of the newborns, an increase of 13.8 percent over the previous two years.

Race

Of total births, 83,504 (77.0%) were reported to occur to white mothers and 22,642 (20.1%) to nonwhite mothers. This was approximately the same proportions as in the previous year. Since 1970 the proportion of total births that were nonwhite has increased slightly, while a comparable decrease has occurred for the proportion of total births that were white. In 1986 this trend reversed itself slightly (less than one percent) from the 1985 figure. Births of unknown or unrecorded race numbered 2,298 (2.1%).

Prenatal Care History

There were 1,133,648 visits for prenatal care. This level of approximately 10.5 visits per patient rose slightly and steadily from the 9.9 visits per patient in 1980. For women giving birth in 1986, 78.2 percent began prenatal care in the first trimester of their pregnancies and only 4.5 percent failed to receive care before the third trimester. Approximately 1.3 percent did not receive any prenatal care.

A greater percentage of white mothers began prenatal care in the first trimester than did nonwhite mothers, and fewer white mothers completed their pregnancies without any prenatal care. Of white mothers, 82.9 percent sought first trimester care. This was a decrease from 83.5 percent in 1985. Nonwhite mothers receiving prenatal care during the first trimester decreased from 69.1 percent in 1985 to 67.7 percent. Nonwhite mothers were nearly three times more likely not to receive any prenatal care than were white mothers (2.8 percent compared to 1.0 percent). Prenatal care for all age-race groups was lowest for nonwhite teenagers with approximately one-half (51.7%) receiving first trimester care, a slight drop from the 53.7 percent in 1985. Of nonwhite teenagers 3.9 percent did not receive any prenatal care, compared to 2.6 percent in 1985.

First trimester care was lowest for teenage mothers. Approximately one-half of the childbearing women in this age group, 5,288 (or 52.0%), received prenatal care from the first trimester of pregnancy. Of the 10,168 teenage mothers, 3.6 percent did not receive any prenatal care, and 8.9 percent did not begin prenatal care until the third trimester of pregnancy. There was a deterioration in the rate of receipt of adequate prenatal care in this age group compared to last year. Data also indicate that attention to prenatal care increases with maternal age. First trimester care was received by 71.0 percent of the women aged 20-24 and 84.1 percent of the women 25 years of age and older.

Educational Trends

Educational level was reported on 94.5 percent of all birth certificates. Three-fourths (78.9%) of mothers were at least high school graduates. Although the percentage of college graduates (22.7%) increased from the 1985 level, the percentage of high school graduates was still below the 1984 level of 82.3 percent. There is an inverse relationship between family size and educational attainment of the mother. Mothers with less education are more likely to already have children when giving birth. Mothers who lack a high school diploma had no previous live births in 42.7 percent of the cases. Among those who completed high school without further education, 44.9 percent had no previous live births. Comparable figures for mothers with some college and for college graduates were 45.9 percent and 48.2 percent, respectively. This relationship becomes more pronounced when comparing mothers who had three or more live births across levels of educational attainment. Of those who earned a high school diploma, 7.2 percent had three or more live births versus 6.2 percent of mothers with some college and 3.9 percent of mothers with college degrees. Among mothers who never completed high school, 13.7 percent had 3 or more live births.

Attendant at Birth

A physician was in attendance at 97.5 percent of all resident births, while midwives attended 2.1 percent of all resident births. The steady rise in midwife attendance since 1980 resumed in 1986, following a 19.4 percent decline between 1984 and 1985. An increase of 11.2 percent occurred among nonwhite mothers assisted by midwives. Midwives attended 1,499 white births, 765 black births, and 42 births to other races.

Mortality 1986

INTRODUCTION

All mortality statistics provided are data summarized from death certificate items filed with the New Jersey State Registrar. New Jersey vital statistics legislation requires a death certificate to be filed by the proper authority for any death occurring within the state. Deaths to New Jersey residents occurring in other states during the calendar year are recorded in the state of occurrence and are covered in this report. These records are forwarded to the New Jersey State Registrar as part of a national exchange program among the 50 states. The Cooperative Health Statistical System is sponsored by the National Center for Health Statistics. Participation in this system involves the reporting of all deaths occurring in New Jersey and forwarding data for the National Death Index.

All death data are maintained on computer tapes by the Bureau of Vital Statistics. Monthly and annual death tabulations are supplied to the Center for Health Statistics for surveillance and reporting purposes. To maintain confidentiality, all individual identifiers are removed prior to tabulation of any data for statistical purposes.

STATISTICAL OVERVIEW

Number of Deaths

As might be expected with the population of the State increasing by twenty-five percent since 1960, the number of resident deaths has likewise increased. The increase in deaths, however, was not in direct proportion to the population increase, which occurred at a much faster pace. The mortality rate was lower in 1986 than in 1960, 9.4 versus 9.8; nevertheless, the total number of deaths was 20.2% higher than the 1960 total of 59,330. Total resident deaths during 1986 were 71,299, an increase of 644 over 1985. There were 31,377 white male deaths, 31,085 white female deaths, 4,901 nonwhite male deaths, and 3,864 nonwhite female deaths.

Mortality Rate

The mortality rate for the State was 9.4 per 1,000 population. Compared to the nation, the New Jersey rate was slightly higher than the national mortality rate of 8.7 per 1,000 population in 1986.

Distribution across the 21 counties varied from a high of 13.6 per 1,000 population in Ocean County to 6.6 per 1,000 population in Sussex County. A ranking by mortality rate indicates that the following counties were higher than the State average: Cape May (13.1), Atlantic (11.7), Hudson (10.4), Cumberland (10.1), Essex and Union (10.0), Warren (9.9), Bergen (9.5), and Salem (9.4).

The New Jersey mortality rate for males (10.1) was higher than the rate for females (8.8). This differential has existed historically. The total white population rate of 9.9 was also higher than the nonwhite rate of 6.8 based on 1,000 deaths per population level. For population groups divided by both race and sex, the highest mortality rate occurred among white males (10.3), and the lowest rate appeared among nonwhite females (5.6).

Age-Specific Rates

Comparisons of age-specific mortality rates for whites and nonwhites show higher mortality rates for nonwhites in age groups under 65 but lower rates for the 65 and above groups. In 1986 the mortality rates for 25-44 year olds were 146.6 per 100,000 for whites versus 356.9 for nonwhites. In the next higher age grouping, 45-64, the rate for whites was 810.2 versus 1,131.1 for nonwhites. The rates for the younger age group were 2.4 times higher for nonwhites, but only 1.4 times higher in the older age groups. Above 65 years of age the nonwhite rate is 0.92 times as high as the mortality rate for whites, 4,804.3 versus 5,217.3. Thus, the chances of surviving another year increase for nonwhites as they age, and elderly nonwhites become more likely to survive than whites.

Age-specific mortality rates for men were higher for all age groups than the corresponding rates for females. In the 15-24 year old age group, the male rate of 115.6 per 100,000 population was nearly 3 times that of the female rate of 38.6 per 100,000 population. The mortality rate for males aged 25-44 (258.8 per 100,000 population) was over twice the rate for females (113.2 per 100,000 population). At ages 45 through 64 males had an age-specific death rate of 1,100.1 per 100,000 population compared to 632.9 per 100,000 for females. The mortality rate for males aged 65 and above was 6,127.1 per 100,000 population compared to 4,581.7 per 100,000 for females.

PRINCIPAL CAUSES OF DEATH

Leading Causes

The ten leading causes of death have remained virtually the same since 1968. In 1986 the leading causes ranked from highest to lowest were: (1) diseases of the heart, (2) malignant neoplasms, (3) cerebrovascular diseases, (4) pneumonia and influenza, (5) accidents, (6) diabetes mellitus, (7) chronic liver disease and cirrhosis, (8) septicemia, (9) nephritis and nephrosis, and (10) diseases of artery, arterioles and capillary.

Deaths caused by diseases of the heart remained approximately at the same level as in 1985 with the mortality rate decreasing by 6.6 points in 1986 to 362.2 per 100,000 population. Malignant neoplasms decreased 0.8% from 1985 to 223.1 per 100,000 population in 1986. Combined diseases of the heart and malignant neoplasms, the two major causes of death, continued to account for almost two-thirds of all deaths in the State. Deaths attributable to diabetes mellitus, nephritis and nephrosis, pneumonia and influenza, septicemia, accidental deaths, and cardiovascular diseases increased, while deaths from malignancies, chronic liver disease and cirrhosis, and cerebrovascular diseases decreased.

Age Groups

Age group data show that accidents were the leading cause of death for the population aged 1-14; malignant neoplasms ranked second. For those aged 15-24, accidents were also the leading cause, and homicide ranked second. For the age group 25-44, malignant neoplasms were the leading cause of death and accidents ranked second, followed by diseases of the heart, suicide, homicide and chronic liver diseases and cirrhosis. For the age group 45-64 malignant neoplasms were the leading cause of death, followed by heart diseases. For deaths to persons aged 65 years and over, diseases of the heart were the major cause of death, and malignant neoplasms ranked second. Cerebrovascular diseases and pneumonia and influenza ranked third and fourth, respectively.

Diseases of the Heart

Diseases of the heart decreased from 27,886 deaths in 1985 to 27,601 in 1986. This slight drop reflected a rate decrease from 368.7 to 362.2 deaths per 100,000 population. There were 12,317 deaths of white males in 1986, a slight decrease from the 1985 level of 12,847. However, total white female deaths increased from 12,536 in 1985 to 12,770 deaths in 1986. Deaths due to heart diseases among nonwhite males also decreased from 1,282 to 1,267 between 1985 and 1986. For the same period nonwhite female deaths increased by 33 from 1,197 to 1,230 deaths. Diseases of the heart remained the leading cause of death for all races, sixty-five years of age or older and for all males forty-five years and older.

Malignant Neoplasms

Malignant neoplasms were the second leading cause of death in 1986 irrespective of race or sex. The crude mortality rates attributable to malignant neoplasms over the past five years are: 1986 (223.1); 1985 (224.8); 1984 (221.7); 1983 (221.8); and 1982 (216.6). Cancer was the second leading cause of death among white males over 44 years of age and those aged 15-44. Cancer was the leading cause of death of white women aged 25-64 and 15-24 and the second leading cause of death for those aged 65 and older. Cancer resulted in the second highest death toll among men and women aged 45 and older, and it was the leading cause of female mortality in the age group 25-44. There was one less death attributable to malignant neoplasms in 1986 than in 1985.

Cerebrovascular Disease

Although cerebrovascular diseases remained the third leading cause of death among New Jersey residents, the number of deaths dropped for the sixth consecutive year. Since 1970 the overall trend has been downward. Eighty-five percent of all deaths from cerebrovascular diseases involved persons 65 years old and over. In 1986 the mortality rates reversed direction for both race and sex. Now the nonwhite population and males are more likely to succumb to cerebrovascular disease. Historically, whites and females experienced the higher rates.

Accidental Deaths

The number of accidental deaths increased from 2,155 in 1985 to 2,176 in 1986 and the death rate increased from 28.5 to 28.6 deaths per 100,000. More deaths were attributed to accidents than to any other cause of death among the total population aged 1-24. Accidents were also the leading cause of death among white males in the 25-44 age group.

Influenza and Pneumonia

In 1986 there were 2,237 deaths in this disease category compared to 2,150 in 1985. Mortality rates for influenza and pneumonia have consistently increased over the past five years. From 1982 through 1986 they were 20.1, 22.7, 26.1, 28.4, and 29.4 deaths per 100,000 population. Influenza and pneumonia taken together caused the fourth largest number of deaths among the elderly (aged 65+), accounting for 1,905 (or 85.2%) of the 2,237 total influenza and pneumonia deaths reported in 1986.

Suicide

There were 662 resident suicides in 1986, a decrease from 1985 (672). The mortality rate dropped to 8.7 per 100,000 from 8.9 in the previous year. The largest number of suicides were by white males, 467. There were 5 white male deaths between the ages of 5 and 14, 81 between the ages of 15 and 24, 192 between the ages of 25 and 44, 97 between the ages of 45 and 64, and 91 for white males aged 65+. Among the nonwhite male population there were 43 deaths. There were 2 recorded for those aged 5-14, 6 for men 15-24, 20 for those aged 25-44, and 14 among those 45 years of age and over. By contrast, the highest age-specific suicide deaths for white females were reported for those aged 25 to 44 and 45 to 64--43 and 54 suicides for each of these two age groups, respectively, during 1986. Only 12 suicides were reported among nonwhite women.

* Suicides are the 18th ranking cause of death among those persons aged 65 and above with 127 deaths from suicide in that age group.
 ** Excludes persons 1 year of age and persons of unknown age.
 *** Ranking 12 not shown for young age groups because of small number of cases in categories.
 **** Deaths from all other causes.

Homicide

Homicide remains a major problem in New Jersey with 459 deaths occurring in 1986. In 1985 there were 452 reported homicides, representing an increase from 435 in 1984 and 447 in 1983. Total homicides and rates per 100,000 population in New Jersey for the three years between 1980 through 1982 were considerably higher, 7.4 and up, than for any previous year. Then the homicide rate declined 18.9% between 1982 and 1983 to 6.0. The homicide rate declined further in 1984 to 5.8, but returned to 6.0 in 1985 and again in 1986. The highest rate of homicides for white males was in the age group 25-44 for which there were 69 cases or 45.1 percent of all white male homicides. The highest percentage of black male homicides also was in the 25-44 year old age group. There were 94 cases or 53.4 percent of all black male homicides. Nonwhite males recorded the highest overall homicide rate at 29.7 per 100,000 population. This rate was almost six times higher than the 5.0 rate for white males. White females recorded the lowest rate at 1.8 per 100,000 population, while nonwhite females had a homicide rate of 9.6 per 100,000 population.

NEW JERSEY HOMICIDE AND LEGAL INTERVENTION 1986

TOTAL		MALE				FEMALE			
No.	Rate**	White		Nonwhite		White		Nonwhite	
No.	Rate**	No.	Rate	No.	Rate	No.	Rate	No.	Rate
459*	6.0	153	5.0	179	29.7	59	1.8	66	9.6

NOTE: *Total includes 2 males of unknown race.

**Rates per 100,000 population.

Legal Intervention (ICD-9 Codes E970-E978) includes injuries inflicted by law-enforcing agents, including military on duty, in the course of arresting or attempting to arrest lawbreakers, suppressing disturbances, maintaining order, and other legal action including legal execution.

Other Selected Causes of Deaths

Diabetes mellitus accounted for 1,248 deaths in 1982, 1,411 deaths in 1983, 1,415 deaths in 1984, 1,398 deaths in 1985 and 1,454 deaths in 1986. The 1985 death rate attributable to diabetes was 18.5 per 100,000 population compared to 19.1 per 100,000 population in 1986.

Chronic liver diseases and cirrhosis accounted for 1,012 deaths in 1986, compared with 1,136 deaths in 1985, 1,032 deaths in 1984 and 1,132 deaths in 1983. The death rate attributable to chronic liver disease and cirrhosis fluctuated as follows between 1983 and 1986: 15.2, 13.7, 15.0, and 13.3 per 100,000 population.

Other diseases of the arteries, arterioles and capillaries produced 726 deaths in 1986 compared with 712 deaths in 1985. The mortality rate for these diseases increased to 9.5 deaths per 100,000 population in 1986 from 9.4 in 1985. Deaths from atherosclerosis numbered 626 in 1986 and 682 in 1985. The corresponding rates per 100,000 population were 8.2 and 9.2.

Bronchitis, asthma and emphysema deaths rose from 607 in 1985 to 654 in 1986. The corresponding death rates for these two years were 8.0 and 8.6 per 100,000 population.

INFANT, FETAL AND MATERNAL DEATHS

Infant Deaths

Infant mortality refers to deaths within one year following birth. Its rate is calculated by the number of infant deaths per 1,000 live births. In 1986 the number of infant deaths was 1,055, compared to 1,113 in 1985 and 1,090 in 1984. The infant mortality rate was 9.7 per 1,000 live births in 1986, a decline from 10.6 per 1,000 live births in 1985 and 10.8 per 1,000 live births in 1984. The 1986 infant mortality rate for the United States was 7 percent higher than that for New Jersey, 10.4 per 1,000 live births. Overall, infant deaths have been on a downward trend since the Department of Health started to collect and maintain statistical records in 1879.

Certain high risk groups can be identified that experience high mortality rates, for example, infants of women who are not white. During 1986 there were 642 white and 403 nonwhite infant deaths, as well as 10 for whom race was unknown. The infant mortality rate for whites was 7.7 per 1,000 live births down from 8.8 in 1985. Among nonwhites the infant mortality rate was almost twice the white rate, 17.6 infant deaths per 1,000 live births in 1985 and 17.8 in 1986.

Infant deaths due to respiratory distress syndrome were again in first place among the top 10 causes of infant deaths. They increased by 5 cases from 139 to 144, or 3.61%, between 1985 and 1986. Other respiratory conditions of the fetus and newborn, and, other and unspecified congenital anomalies were among the ten leading causes of infant deaths that also showed a percentage increase. Second place was claimed by other respiratory conditions of the fetus and newborn and experienced an increase of 50 percent. Disorders related to short gestation and unspecified low birthweight, the second ranking cause of infant death in 1985, decreased by 17 cases and ranked third in 1986.

PRINCIPAL CAUSES OF INFANT MORTALITY 1985-1986

CAUSE DESCRIPTION (ICD-9 CODE)	1986		1985		Percent Change
	Rank	Number	Rank	Number	
Respiratory Distress Syndrome (769)	1	144	1	139	+3.6
Other Respiratory Conditions of Fetus and Newborn (770)	2	108	5	72	+50.0
Disorders relating to short gestation and unspecified low birthweight (765)	3	106	2	123	-13.8
Sudden Death, Cause Unknown (SID's) (798)	4	102	3	105	-2.9
Other and Ill-defined Conditions Originating in Perinatal Period (779)	5	79	4	100	-21.0
Other Congenital Anomalies of Heart (746)	6	50	6	56	-10.7
Other and Unspecified Congenital Anomalies (759)	7	31	11	28	+10.7
Intrauterine Hypoxia and Birth Asphyxia (768)	8	27	10	29	-6.9
Congenital Anomalies of Respiratory System (748)	9	25	7	39	-35.9
Infections Specific to the Perinatal Period (771)	10	24	8	34	-29.4

NOTE: ICD-9 Code 779 includes 779.6, termination of pregnancy.

Neonatal Deaths

Statistics show that most infant deaths occur during the first month of life. These infant deaths are referred to as neonatal deaths. In 1986 there were 708 neonatal deaths, a decrease of 51 since 1985. The 1986 neonatal mortality rate was 6.5, a decrease of 0.7 per 1,000 live births from the 1985 level of 7.2. New Jersey's 1986 neonatal mortality rate is 0.2 less than the national rate of 6.7 per 1,000 live births. In 1986 there were 445 white and 254 nonwhite neonatal deaths recorded, along with 9 of unknown race. The neonatal mortality rates for whites and nonwhites were 6.3 and 10.8, respectively, in 1985. In 1986 the rates were 5.3 and 11.2, respectively, indicating that the rate for whites decreased by 18.5 percent over this period while the rate among nonwhite mothers increased by 3.7 percent.

Fetal Deaths

A fetal death is defined as a death occurring prior to complete expulsion or extraction of a fetus from its mother as a product of conception. Other commonly used terms are stillbirth and spontaneous abortion. Fetal deaths occurring after the completion of twenty or more weeks of gestation are required by law to be reported to the State Registrar.

The reported number of fetal deaths and the corresponding fetal death rate have declined over the past twenty-five years. In 1958 there were 2,185 fetal deaths with a rate of 16.8 fetal deaths per 1,000 live births. In 1986 there were 1,166 fetal deaths or 10.8 per 1,000 live births. However, all of this decline in fetal deaths was achieved prior to 1975 when 941 fetal deaths were reported, producing a rate of 10.3. The lowest level of fetal deaths was recorded in 1983; the number of fetal deaths was 839 and the rate was 8.5 per 1,000 births.

The number of white fetal deaths increased from 491 in 1983 to 654 in 1984, then rose to 707 in 1985 and to 766 in 1986. Nonwhite fetal deaths increased from 323 to 374, then decreased to 335 between 1983 and 1986. The fetal death rate for the white population increased 46 percent from 6.3 in 1983 to 9.2 per 1,000 live births in 1986. For the nonwhite population, the rate increased by 14.2 percent from 15.5 in 1983 to 17.7 in 1984, then declined by 16.3 percent to 14.8 per 1,000 live births in 1986.

Perinatal Deaths

Perinatal mortality is a composite statistic used to measure the critical period in human development just prior to birth and shortly thereafter. Perinatal mortality includes fetal deaths of 20 weeks or more gestation plus neonatal deaths (infant deaths within 28 days of birth). During the last twenty-five years perinatal deaths have declined dramatically. The perinatal mortality rate in 1958 was 34.4 and has declined to 17.1 in 1986.

There were 1,874 perinatal deaths in 1986, a decrease of 4 from 1985. However, the perinatal mortality rate decreased from 17.6 to 17.1 deaths per 1,000 live births. The long-term trend shows a substantial drop over the last fifty years with minor fluctuations recorded for the short term. Perinatal mortality rates for whites and nonwhites were 14.5 and 26.0 per 1,000 live births, respectively, for 1986. The rate for whites was a decrease from the 1985 rate of 15.0; the rate for nonwhites was a decrease from 27.1 per 1,000 births.

Maternal Deaths

Maternal deaths have declined dramatically since 1940 when the number of deaths was 172 and the rate was 29.0. In 1986 there were 10 maternal deaths with a corresponding rate of 0.9 per 10,000 live births. This level follows the 1985 figure of 3 maternal deaths with a rate of 0.3 which was the lowest both in number and rate to date. The previous low occurred in 1981 and 1983: 5 deaths with a rate of 0.5.

Marriages/Divorces 1986

INTRODUCTION

Marriage statistics provided in this report were tabulated from items reported on marriage certificates filed with the New Jersey State Registrar for calendar year 1986. Divorce data were obtained from the New Jersey Superior Court, Chancery Division. Both marriages and divorces are recorded by place of occurrence or judgment. Therefore, statistics presented refer to the number of events occurring within New Jersey irrespective of place of residence of the participants. Rates published in this report for both marriages and divorces are based on the 1986 New Jersey annual estimates of population released by the New Jersey Department of Labor.

STATISTICAL OVERVIEW

Number of Marriages

The number of marriage certificates issued in New Jersey during 1985 and again in 1986 showed decreases from the 1984 high which was the highest level recorded since the start of marriage statistical reporting. The 1984 level surpassed the 1946 high of 61,020, the year following the end of World War II. The number of marriages for 1985 was 61,189, a decrease of 1,465 from 1984. The number of marriages in 1986 was 61,362. These numeric declines were enough to decrease the rate of marriages per 1,000 population in 1985 and 1986 to 8.1 from 8.3 in 1983 and 1984. The 1983 and 1984 rates were the highest marriage rates per 1,000 population attained since 1951 (when the level was 8.9 per 1,000 population). A low in the number of marriages and the corresponding rate per 1,000 population was reached in 1977; since then both have been increasing. The overall gain from the 1977 level was 17.4%.

The greatest number of marriages occurred in Essex County (7,319) with the lowest number recorded for Salem (472). Six of the state's counties accounted for over 50 percent of the marriages during 1986. All of these counties recorded 4,000 or more marriages; in descending order they are Essex (7,319), Bergen (6,553), Middlesex (4,982), Hudson (4,881), Monmouth (4,534), and Passaic (4,118). In 1986 Cape May County recorded the highest marriage rate, 9.3 per 1,000 population, followed by Atlantic, Passaic, Hudson, and Essex. Ocean County had the lowest rate, 6.5 per 1,000.

Previous Marital Status

Data on marital status showed that the proportion of men to women previously married has remained stable over the past four years. The increase in first marriages between 1985 and 1986 was 0.2 percent for women and 0.4 percent for men. Sixty-three percent of all marriages were between persons marrying for the first time; in 74.5 percent of all marriages the woman was marrying for the first time. Divorced men were marrying in 25.0 percent of all marriages, and divorced women were marrying in 23.0 percent of all marriages.

Age

In 1986 the average age at time of marriage (regardless of previous marital status) was 27.6 years for women and 30.1 years for men, a decrease for both sexes since 1985. The mean ages in 1985 were 27.8 years for women and 30.3 years for men. The number of women and men marrying before the age of 25 continues to decline. In 1986 40.0 percent of the women married before the age of 25, compared to 42.3 percent of the women in 1985, 43.8 percent in 1984, and 46.3 percent in 1983. The same pattern also applied to men marrying before the age of 25 -- 26.2 percent in 1986 versus 27.8 percent in 1985. In 1981 comparable figures were 35.8 percent or 20,793 males marrying before age 25. Teenage brides, likewise, continued their downward trend to a level of 4,077 compared to 4,382 in 1985 and 4,997 in 1984. Teenage brides comprised 6.6 percent of all brides in 1986, compared to 7.2 percent, 8.0 percent and 8.9 percent in 1985 through 1983, respectively.

DISSOLUTION OF MARRIAGE

For every two marriages during 1986, one divorce occurred. There were 27,669 divorces and annulments during the 1986 calendar year. This was a total of 1,626 less than in 1985. Since the marriage rate remained constant, the decrease in divorces raised the ratio of marriages to divorces. The marriage dissolution rate, the number of dissolutions per 1,000 population, reached 4.1, an all-time high, in 1982. In 1983 and 1984 the rate returned to the 1981 level of 3.8 per 1,000 population. In 1985 the marriage dissolution rate increased slightly to 3.9. However, in 1986 the marriage dissolution rate dropped to 3.6.

The ratio of divorces to marriages differed little among the counties. While the order was slightly different, the top ranking seven counties were the same as in 1984. These counties, Bergen, Essex, Middlesex, Monmouth, Hudson, Camden and Union, accounted for over 55 percent of the dissolutions that took place.

Municipality Gross Summary 1986

INTRODUCTION

Annually, the New Jersey Department of Health has produced County tables with individual Municipality summaries of marriages, births and deaths (infant, fetal, neonatal). These tables also include the latest population totals for each Municipality released by the New Jersey Department of Labor, Office of Demographic and Economic Analysis.

These special County-Municipality tables were originally produced to provide vital statistics information to local health officers and various programs within the Department of Health. Increased requests for these tables have been received from researchers and the public. Thus, this section presents the seven above-mentioned items in one table summarizing data for each of the 21 counties and 567 municipalities in New Jersey. Crude birth or mortality rates are not included; they are presented elsewhere in this report for the State and for each of the 21 counties.

-
- NOTE: ¹ Infant Death refers to a death occurring to a live born individual of less than 1 year of age.
- ² Fetal Death is defined as death prior to the complete expulsion or extraction from its mother of a product of conception; the fetus shows no signs of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.
- ³ Neonatal Death refers to a live born infant who dies before completing four weeks (28 days of life).
-

ESTIMATED POPULATION, MARRIAGES, BIRTHS, DEATHS, INFANT DEATHS,
FETAL DEATHS AND NEONATAL DEATHS BY COUNTIES
1986

Fertility 1986

THE AMERICAN WOMEN

In the U.S. the fertility rate, which expresses the number of live births to women aged 15-44 per 1,000 women in this childbearing age, decreased about two percent between 1985 and 1986 (66.2 and 64.9 respectively). The 1986 rate was the lowest rate thus far recorded. Furthermore the U.S. fertility rate has remained essentially unchanged throughout most of the 70's and 80's. The fertility rate for 1985 was 1,842.5. Thus, if 1,000 women experienced the age-specific birth rates for 1985 over their entire childbearing span, they would be expected to average 1.8 children per woman.

It is not certain whether the recent stability in birth expectations is transitional and will lead to a further decline in fertility, or whether it indicates a new demographic trend in the United States. If the latter proves to be the case, the pattern of American fertility in future years will follow that of many Western European nations and Japan, namely, small fluctuations in fertility around the level needed for the natural replacement of the population (approximately 2.1 children per woman).

From marriage data it is known that in recent years there has been an increasing tendency for women to delay their first marriage and first birth to later years. Of those women who first married between 1965 and 1969, 69 percent married by age 21; this proportion declined to 60 percent for women who first married during the 1976-80 period. The median age at first marriage has risen for both sexes since 1965; in 1981 the median ages were 22.0 years for females and 23.9 years for males. In addition, 56 percent of all first births between 1965 and 1969 occurred to women less than 22 years old; this percentage dropped to 47 percent between 1976 and 1980 for women having their first birth.

The longer a woman postpones childbearing after her first marriage, the less likely she is to have any children at all. In 1982, 20.4 percent of ever married women between the ages of 15 and 44 were childless, compared to 18.8 percent in 1980. Furthermore, fewer married women are having children before reaching twenty. The percent of ever married women who remained childless from ages 15-19 has increased from 46.6% in 1980 to 52.8% in 1981 to 57.4% in 1982.

THE NEW JERSEY WOMEN

Fertility patterns of New Jersey women of childbearing age have shown several changes in trend. The decade of the forties was the end of a long period of declining fertility. In the fifties fertility rates increased steadily reaching their highest levels. In 1960 we had 9.8% fewer women aged 20-24, for instance, than in 1950. However, the State had approximately 12,328 more births in this age group, a 45% increase in births. In the 1970s the fertility rate decreased from a 1970 high of 81.2 per 1,000 women to a level of 55.2 per 1,000 in 1976. The 1986 level indicates a fertility rate of 60.4 per 1,000 women.

The fertility rates over the past 30 years have changed most dramatically for women 20-24 years of age. From the 1950 level of 151.1 births per 1,000, the rate rose to 240.6 by 1960. This represents an increase of nearly 90 per thousand. During the decade of the sixties the decline was equally dramatic dropping from 240.6 per thousand to 154.8 in 1970. This placed the rate back almost to the 1950 level. The 1970 to 1980 period showed a low of 67.0 per thousand for this age group of 20 to 24 year olds. The 1986 rate is 78.5 per thousand, a decrease from 87.0 per thousand in 1980.

A review of all age groups shows that the change since 1960 is a reversal to lower fertility rates. The fertility rates by individual age groups ranged in 1960 from a rate of 34.8 for women 35 years and older to 58.3 for those under twenty. In 1980, the range was from 12.5 (35 years +) to 35.2 for those under 20. The rates for all ages are now below the 1970 rates, but in New Jersey the fertility rates for 1986 were slightly increased over 1985 for women aged 15-19 and 25-44.

New Jersey's present uptrend in fertility rates is contrary to the national trend. U.S. fertility rates were 66.1 per 1,000 women in 1985 and 64.9 per 1,000 women in 1986. Fertility rates in New Jersey were 59.2 and 60.4 per 1,000 women for the same two years. New Jersey's lower fertility rates are attributable, in part, to the older age structure of the female population.

The age-specific fertility rates for younger women aged 20 to 24 in New Jersey have been declining over the period 1980 to 1986, while over that same time period the age-specific fertility rates for women aged 25 and over have been increasing. The crossover in these trends implies that childbearing is occurring later, possibly for socio-economic reasons.

With the use of age-specific fertility rates it is possible to calculate the "total fertility rate" (TFR) which summarizes the changes in fertility. The rate is computed by summing the age-specific rates for all childbearing ages and multiplying by the number of years in each age group used. In this case the age interval is five (5) representing five ages in each group. It can be interpreted as the number of children that would be born to a cohort of one-thousand women if, at all childbearing ages, they bore children at the age-specific rates observed in the reference year. Considering present death rates and a sex ratio at birth of 106

males per 100 females, it requires a little over 2,100 births per thousand females to replace themselves as child bearers in the next generation. Thus, when the TFR exceeds 2,100, the next generation will have a larger childbearing population than the present one; when the TFR declines below 2,100, the next childbearing generation will be smaller than the present generation.

In 1950 the TFR for New Jersey was close to the replacement value of 2,100. By 1960 it had risen to 3,446. However, by 1970 a drop of 30% brought the level down to 2,408. The decline of the TFR during the sixties was greater than the rise in the fifties. The single year decline between 1970/71 and 1971/72 showed the most rapid decline of any year for which we have detailed data. The TFR appears to have "bottomed out" in the late 1970s, just as the number of births did in the early 1970s. In 1980 the 1,604 value was 30.9% below replacement fertility level. By 1986 however, the rate was again on the rise, reaching 1,737. Since the number of marriages in New Jersey has increased this year, perhaps the TFR will continue to rise.

Abortions 1986

INTRODUCTION

The Department of Health collects data on induced abortions performed in all licensed abortion facilities in the State. Abortions performed in hospitals and licensed outpatient abortion facilities must be reported to the Department within 10 days after the close of the month in which the procedure was performed. Forms are provided by the Department and are processed monthly. A yearly summary report is also compiled. The form is designed to provide data which can serve as a basic resource for health services decisions relating to abortions, such as planning abortion services and providing family planning services. Data collected include information on the woman's age, marital status, municipality of residence, race, prior number of pregnancies and prior live births. Clinical information is limited to gestation period at termination and method of termination. Patients' names are never reported to the Department; therefore confidentiality is maintained.

This report includes a narrative summary which presents related clinical information and demographic characteristics of the women receiving abortions in 1986. The statistics presented in this report represent induced abortions occurring only in licensed New Jersey health care facilities. Data can be obtained for residents obtaining abortions in other states from the National Center for Disease Control, Atlanta, Georgia.

OVERVIEW

Selected Characteristics

The number of reported induced abortions performed in New Jersey was 33,376 in 1986 compared to 31,266 in 1985, 31,236 in 1984, 24,722 in 1983 and 30,269 in 1982. The increase from 1985 to 1986 was 6.7 percent. However, the percentage change between 1984 and 1985 was inconsequential. The percentage increase from 1983 to 1984 was 26.3 percent compared to the 18.3 percent decline from 1982 to 1983. In 1986, women who obtained an induced abortion in New Jersey were predominantly state residents (97.2%). The majority of women were Caucasian (43.9%) and 37.4 percent were Black. The average age among women receiving induced abortions in 1983 was 24.6 years compared to 24.4 years in 1984 and 24.5 years in 1985 and 1986. Most of the women (77.0%) were unmarried, less than 25 years of age (59.0%) and childless (50.1%). The majority of abortions (83.2%) were performed during the first trimester by sharp or suction curettage (99.9% of first trimester cases and 97.3% of all cases). As in previous years, a licensed outpatient abortion clinic was the primary setting used in 1986 and accounted for nearly three-quarters (71.8%) of all abortions performed and 70.8 percent of the first trimester procedures.

Age

Over one-third of the 1986 abortions were performed on women between the ages of 20-24. Nearly one-fourth were performed on women aged 15-19, while slightly over one-fifth were performed on women ages 25-29. The under 15 and over 44 years categories accounted for less than 1.5% of the 33,376 abortions in 1986. However, the ratio of induced abortions to live births (defined below) for these two age groups was notably higher than for the in-between ranges. Their rate of abortions to live births has fluctuated greatly from 1,155 per 1,000 births in 1983 to 1,634 in 1985, dropping to 1,323 in 1986. The 25-29 and 30-34 year old age groups experienced the lowest abortion to live births ratios, 200 and 147, respectively, down from 188 and 140 in 1985. The 1986 abortions to births ratio for New Jersey women was 315 per 1,000, a slight increase from 305 in 1985; another way to express this ratio is one abortion per 3.2 live births.

The abortion ratio is defined as the number of women obtaining legal abortions divided by the number of women giving birth in the population in the same year with the same demographic characteristics (such as residence, age, race, marital status, or number of previous live births) times 1,000. The purpose of this ratio is to locate where in the life cycle with respect to either age or previous number of live births, for example, women are more likely to receive an induced abortion than at other points in the life cycle.

Race

The women having induced abortions in 1986 were self-reported as 43.9% white, 55.4% nonwhites and 0.7% unknown. In 1986 these percentages highlight a trend in recent years which resulted in a 9.5% percent decline for 1986 in the percentages of whites and an identical increase in relative numbers of nonwhites who have obtained induced abortions. In 1979, the percentages of white women equaled 64.4%, dropping to 60.4% in 1980, 58.9% in 1981, 54.2% in 1982, 53.2% in 1983, 51.1% in 1984, 48.5% in 1985 and 43.9% in 1986. Black women who had induced abortions increased from 26.2% in 1980 to 37.4% in 1986.

The ratio of induced abortions to live births decreased between 1982 and 1983 for both whites and nonwhites, increased between 1983 and 1984 and decreased between 1984 and 1985. In 1986, the ratio decreased for whites but increased for Blacks. For white women, the ratio declined from 219 to 174 between 1982 and 1983, and then rose to 207 in 1984. In 1985 it dropped to 189 and in 1986 it fell to 176. The same ratio fluctuated for black females dropping from 518 to 445, then rising to 631 induced abortions per 1,000 live births over the years 1982 to 1986.

Marital Status

Unmarried women had 77.0 percent of the total induced abortions in 1986. The two age categories which accounted for slightly over one-half were unmarried women aged 15-19 (23.1%) and unmarried women aged 20-24 (28.9%). Married women who received abortions exceeded those for unmarried women in all age groups after age 34. There were 51.9 percent more married women than unmarried women who were over 34 and had induced abortions.

Prior Number of Live Births

Abortion data reported for 1986 indicated that half (50.1%) of women had never given birth at the time of pregnancy termination. Almost one-quarter (24.1%) of the women indicated having one previous live birth, and 17.1 percent had two previous live births. Fewer than one in ten (6%) were listed with three or more births.

The lowest induced abortions per 1,000 live births ratio (231) was computed for women who had one previous live birth. Women with three previous live births had the highest ratio of abortions to live births (403 per 1,000); women with two or four previous births had very similar ratios (378 and 362 respectively).

Place of Residence

The majority of women (97.2%) who elected to have an abortion in New Jersey were in-state residents. Essex was the most frequent place of residence (26.4%) with the lowest (0.1%) recorded in Salem County. More than one-half of the abortions in 1986 were obtained by women who indicated Essex (26.4%), Hudson (15.3%), Bergen (7.9%), or Passaic (6.8%) as counties of residence. Correspondingly, these areas rank as the four most heavily populated counties in New Jersey. In 1986 Hudson County experienced the greatest increase in the number of abortions performed, an increase of 1,517 cases. This was also the largest percentage increase in abortions, 42.1%. The greatest decrease in the number of abortions performed in 1986 was in Bergen County, a decline of 239 cases or 8.3%. The greatest percentage decrease occurred in Hunterdon County, 17.4% or 33 cases.

For the 1986 reporting period, out-of-state women who had abortions originated from twenty three states, the District of Columbia and several foreign countries. The border states of New York and Pennsylvania were most frequently represented. New York State residents accounted for 61.4 percent (580) of all nonresident abortions while Pennsylvania residents represented 31.5 percent (298) of the total.

Type of Procedure

The types of procedures most frequently reported were suction curettage (79.1%) and sharp curettage (18.2%). These two procedures accounted for nearly all (99.9%) reported first trimester abortions and 99.1 percent of the procedures performed between the 13th and 15th weeks of pregnancy. Saline instillations represented 2.5 percent of all reported induced abortion procedures. Abortion induced by saline instillation or administration of the drug Prostaglandin occur primarily after the 16th week of gestation. Saline instillations accounted for 68.8% of all abortions performed during the late second trimester, and Prostaglandin administrations accounted for 7.5%. The use of Prostaglandin increased in 1986 from 3.8% in 1985, a reversal of a downward trend since 1981 when 8% of late second trimester abortions were performed using Prostaglandin. The use of suction curettage during the period between the 16th and 20th weeks of gestation is increasing. Suction curettage was used in 41.4 percent of the cases occurring between 16 and 20 weeks, compared to 26.1 percent in 1985, 26.7 percent in 1984, 13.9 percent in 1983 and 1.3 percent in 1982. In contrast, the percentage of saline instillations has declined during the same period. More sharp/suction curettages were performed than saline instillations for the 16th through 20th weeks of gestation since 1982. It should be noted that the period between 16 and 20 weeks of gestation includes two relatively distinct stages of pregnancy requiring different abortion procedures.

Weeks of Gestation

Of the 33,376 reported induced abortions in 1986, 83.2 percent were completed during the first trimester of pregnancy, almost identical to 1985 (83.4 percent). The proportion of abortions performed during the 13th to 20th weeks increased slightly from the 15.3 percent in 1985 to 16.3 percent in 1986. One hundred sixty women (0.5%) underwent a late second trimester abortion (over 20 weeks) compared to 1.4 percent in 1985 and 1984.

More than one-third (34.1%) of all first trimester abortions were performed on women in the 20 to 24 age group. Percentages for women aged 15-19 were 21.5% and 22.8% for women aged 25-29. Women who terminated pregnancy in the 13th to 20th week of gestation were most frequently aged 15-19 (35.8%), and one-third (34.4%) were in the 20-24 age range. Of the women estimated to be more than 20 weeks pregnant at the time of the reported abortion, 31.9 percent were in the age group 15-19, and 23.0 percent were 20-24 years old. The same figures for 1985 were 35.4 percent and 32.1, respectively. There were four women between the ages of 40 and 44 in the over 20 weeks gestation classification, and 21.9% of the women were between the ages of 30 and 44 years.

Type of Facility

The 1986 data on induced abortions were collected from hospitals and licensed outpatient abortion facilities. The percentage of abortions performed in hospitals increased steadily from 1979 to 1981 and decreased, though unevenly,

since then. In 1979, 28.6 percent of abortions were performed in a hospital setting, 32.6 percent in 1980, 38.1 percent in 1981, 36.0 percent in 1982, 37.9 percent in 1983, 34.0 percent in 1984 and 34.2 percent in 1985, and 28.2 percent in 1986. Outpatient facilities accounted for 71.8 percent of the 33,376 reported abortions in 1986. Most (88.6%) of the 13 to 15 week pregnancy terminations were completed in a licensed outpatient facility along with 70.8 percent of all reported first trimester abortions. All (with the exception of two) pregnancy terminations performed after 20 weeks and 31.0 percent of those completed during the 16th to 20th week were reported by hospitals. In 1983, 51.7 percent of those abortions performed during the 16th to 20th week were performed in hospitals. Of all single women who had an abortion in 1986, nearly three-quarters (73.5%) went to clinics. Married women were more likely to use an outpatient facility in 1986: 67.3% of married women had procedures in outpatient facilities compared to 62.6% in 1985 and 61.6% in 1984.

Number of Previous Abortions

Information submitted indicated that most women (53.6%) had never undergone a previously induced pregnancy termination. Slightly over one-fourth (28.9%) of the women had obtained one previous abortion, and 17.4% reported two or more past abortions. A comparison with two earlier years shows a similar likelihood to present for first abortion (55.2% had first abortions in 1985, while 57.0 percent had their first abortion in 1984), indicating that recidivism is not increasing.

ABORTION REPORTING GUIDELINES

The Department of Health in cooperation with the State Board of Medical Examiners, the New Jersey Obstetrical and Gynecological Society, and the Medical Society of New Jersey have adopted the following guidelines (applicable to abortion data) which were made necessary by the United States Supreme Court's decision regarding abortion:

1. Only persons licensed as physicians are permitted to perform abortions.
2. First trimester abortions (on or before the 12th week of pregnancy) may be performed only by qualified physicians in their private offices (if the patients medical condition permits) or in licensed health care facilities (i.e., hospitals or outpatient abortion clinics).
3. Beyond the first 12 weeks and within a period of gestation not exceeding 16 menstrual weeks and/or 14 gestation weeks (size as determined by a physician) termination of pregnancy using the dilation and evaluation procedure can be performed either in a licensed hospital or outpatient abortion clinic; if any other method of abortion is utilized to terminate a pregnancy during this time it must be performed in a licensed hospital on an inpatient basis.
4. Termination of a pregnancy after the 16th menstrual or 14th gestation week will only be performed in a licensed hospital on an inpatient basis.
5. Third trimester abortions are allowed only to preserve the life or health of the mother, or where it has been determined late in pregnancy that there is a nonviable or deformed fetus incapable of extrauterine survival.

Communicable Diseases 1986

INTRODUCTION

Overview

In previous years the Morbidity section of the Health Statistics Report has reported the occurrence of communicable diseases throughout the state. For the first time in New Jersey Health Statistics 1985, communicable diseases were reported in a section titled Communicable Diseases. This newly created section also reported Acquired Immunodeficiency Syndrome (AIDS) cases and deaths.

The Communicable Diseases section reports on those diseases declared by law under the New Jersey State Sanitary Code to require notification of their occurrence to the Department of Health. As provided by Regulation 8:57-1.14 both AIDS and AIDS Related Complex (ARC) became legally reportable diseases on October 6, 1986. Statewide reporting of these diseases involves various programs throughout the Department of Health, each of which collect and compile the data. The Tuberculosis Program collects information on all tuberculosis cases occurring in New Jersey through their monitoring and surveillance activities. Incidence data on syphilis and gonorrhea are collected by the Sexually Transmitted Disease Program. AIDS and ARC cases are reported to the AIDS Surveillance Program within the Division of Alcohol, Narcotic and Drug Abuse Control. Data on other Communicable Diseases are reported to the Communicable Diseases Program within the Division of Epidemiology and Disease Control. Requests for details and specific information regarding each disease should be addressed to the appropriate program.

COMMUNICABLE DISEASES

Statistical Overview

The population used for computing rates in this report represents the estimated population residing in the state, its 21 counties and 562 municipalities as of July 1, 1986. These estimates are obtained from the Office of Demographic and Economic Analysis, Division of Planning and Research in the Department of Labor.

The age and sex-specific rates for syphilis, gonorrhea and hepatitis presented in this report were computed thusly. The number of deaths in a disease category for a specific age and/or sex group was divided by the state's estimated population of persons in the same age and/or sex group. The results are presented as rates per 100,000 estimated population for each age and sex group.

Tuberculosis

In 1953 there were 4,189 diagnosed cases of tuberculosis or 79.9 cases per 100,000 population. By 1980 newly diagnosed cases had dropped to 980 or nearly 13.3 per 100,000 population. This long term, substantial decline in the number of new cases slowed in 1981 when 1,028 cases were recorded yielding a rate of 13.9 cases per 100,000 population. From 1982 to 1984 small increases in the number of cases were reported each year. In 1985 the number of cases dropped to 839 from 935 in 1984, a 10.3 percent decrease. The 1985 rate of 11.1 per 100,000 population was the lowest ever. However, in 1986 the number of cases rose to 984. The rate per 100,000 population was 12.4. The annual number of deaths attributed to tuberculosis has followed a similar pattern dropping from 693 deaths in 1953 to 62 deaths in 1985. The mortality rate per 100,000 population dropped from the 1953 level of 13.2 to less than one death (0.8) per 100,000 in 1985. However, in 1986 the number of deaths increased to 78 with the rate reaching 1.0 per 100,000.

In 1983 there were 809 clinically active and verified cases of tuberculosis in the New Jersey population. This level dropped in 1984 to 790 and dropped again in 1985 to 545. This fluctuation continued in 1986 when the number of cases climbed by almost a third (32.8%) to 724. From an active rate of 10.9 per 100,000 population in 1983, the rate of active cases dropped to 10.5 statewide in 1984, then down to 7.2 in 1985 before rising to 9.2 in 1986. Among the larger cities in New Jersey, tuberculosis morbidity rates were highest for Patterson (38.1), Newark (37.6), Jersey City (33.9), and Elizabeth (33.8).

While decreases over the past few years have occurred in the number of clinically active cases across the state, at the county level there have been both increases and decreases. From 1985 to 1986 the situation changed significantly with decreases occurring in six counties and increases in fourteen counties. The most notable increases were recorded in Hudson County (12.2 to 20.1), Passaic County (11.3 to 18.0), Union County (8.5 to 13.9), Cumberland County (2.2 to 8.1) and Mercer County (3.1 to 9.9). Significant decreases occurred in Atlantic County (12.7 to 10.7) and Sussex County (5.0 to 3.3).

Venereal Disease

During the last twenty years the number of syphilis cases among residents of New Jersey has decreased dramatically. In 1963 there were 5,613 reported cases of syphilis compared with 2,636 cases in 1972. In 1982 the reported cases decreased to 1,930. In 1983, however, the number of cases rose to 2,088 - an increase of 8.2%. A further decrease of 82 cases occurred in 1984, but the number of cases of syphilis rose to 2,284 in 1985. This striking decrease between 1963 and 1972 was basically a reflection of improved methods of tabulation that resulted in the elimination of duplicate cases. Between 1972 and 1984 a modified reporting system was employed. In 1984 2,006 cases were reported, a decline of 23.9 percent from 1972. The 1985 total of 2,284 cases represents the second sizable increase since 1963. However, in 1986 cases decreased by 12.7% to 1,993. The rate of 26.2 cases per 100,000 population still falls below the 1972 rate of 36.0. The number of primary and secondary cases dropped from 942 in 1972 to 672 in 1986, with a corresponding drop in the morbidity rate from 12.9 to 8.8 cases per 100,000. The number of cases diagnosed as early latent syphilis decreased 9.9 percent during the same period; the rate dropped from 8.3 to 7.2 per 100,000. The 1986 total of 1,993 cases of syphilis included 672 primary and secondary cases and 551 early latent cases.

In contrast to the decline in the number of syphilis cases, the prevalence of gonorrhea has continued to climb during the period under study. The number of gonorrhea cases increased from 3,968 cases in 1963 to 18,837 cases in 1977, nearly a fivefold increase. By 1981 a high of 22,998 cases were reported with the morbidity rate quintupling from 61.0 in 1963 to 310.5 cases per 100,000 population in 1981. Since 1981 the number of cases has steadily decreased, along with the rates. In 1986 there were 19,612 cases or 257.4 per 100,000. Of the total cases of gonorrhea reported, the military accounted for 534 reported cases in 1977. The occurrence of gonorrhea among servicemen had dropped to a low of 153 cases in 1985 but increased to 231 cases in 1986.

Hepatitis

The number of reported cases of infectious hepatitis type A decreased slightly in 1986. There were 383 cases with a rate of 5.0 per 100,000 persons in 1986, as compared to 397 cases and a rate of 5.2 in 1985. Serum hepatitis (B) cases declined by 22.6% in 1986 to 630, and the rate was 8.3. In 1985 the rate was 10.8 with 814 cases. Approximately 59 percent fewer cases of unspecified hepatitis were reported in 1986. The rate of infection dropped from 1.2 in 1985 to 0.8 per 100,000 persons in 1986. Hepatitis incidence is higher for men than for women for all types of hepatitis. In 1986 there were 6.3 cases of infectious hepatitis per 100,000 men versus 3.9 cases for every 100,000 women. The male rate for serum hepatitis was 10.8; for females the rate was 5.9. A total of 36 cases of hepatitis (unspecified) were reported among men (1.0 per 100,000), but only 22 cases among women (0.6 per 100,000). Among both men and women there were 137 cases of infectious hepatitis in the age group 20-29 years and 83 cases in the age group 30-39 years. The highest incidence of serum hepatitis was reported among persons aged 30-39 (156 cases). The next highest incidence occurred among those aged 25-29 (148 cases). The corresponding incidence rates for the two age groups were 13.0 and 23.3, respectively. The year 1983 brought with it a change in the reporting of hepatitis. A new category, type non-A and non-B, was added. For type non-A, non-B hepatitis a decline occurred in 1986. The incidence rate dropped to 0.8 per 100,000 persons (63 cases) from 1.3 per 100,000 persons in 1985 (101 cases).

Other Notifiable Diseases

As required by law the occurrence of contagious diseases must be reported to the Department of Health. These diseases include mumps, measles (rubeola), German measles (rubella), typhoid fever, malaria, aseptic meningitis, and a host of other communicable diseases. In both 1985 and 1986 the magnitude of these disease conditions showed marked declines, while a few notable increases occurred.

The number of cases of measles (rubeola) increased from 30 in 1985 to 881 in 1986. The number of cases of measles, typically fluctuates widely from year to year. In 1976, for example, 690 cases were observed while in 1974 there were 5,693 cases. About a decade ago the number of cases of rubella was 1,483 in 1976. In 1986 only 4 cases of rubella were reported. Salmonellosis cases (excluding typhoid fever) rose slightly in 1986; there were 2,567 cases reported versus 2,354 cases in 1985. There were 495 cases of shigellosis (bacillary dysentery) in 1985 and 375 cases in 1986. Most shigellosis cases occurred in the counties of Essex (69), Passaic (65), and Middlesex (53).

The number of cases of mumps decreased to 51 in 1986 from 57 in 1985. The highest number of cases reported in 1986 occurred in Bergen and Gloucester counties (6 cases each). Other diseases reported were: amebiasis, 84 cases, of which 40 cases were reported in Cape May County; aseptic meningitis, 280 cases; legionellosis, 30 cases; malaria, 36 cases; meningococcal infections, 77 cases; pertussis, 20 cases; tetanus, 4 cases; tularemia, 2 cases; typhoid fever, 11 cases; typhus fever, 2 cases; toxic shock syndrome, 28 cases; and encephalitis (Other Primary Infections), 11 cases.

Acquired Immunodeficiency Syndrome (AIDS)

The era lauded for its control of major infectious diseases was interrupted decisively in 1981 by the identification of a new and deadly contagious illness, Acquired Immunodeficiency Syndrome (AIDS). In the late 1970's the first human retrovirus was isolated and labelled human T-lymphotropic virus type I (HTLV-I). By 1984 human retroviruses that are known to cause AIDS were isolated and labeled human immunodeficiency virus, HIV-I and HIV-II. As reasearch continues, still more of these kinds of viruses are being identified. The AIDS viruses appear to be transmitted through one or more of four routes: sexual contact, intravenous drug use with contaminated needles, the administration of blood and blood products, and the passage of the virus from infected mothers to their newborns. In New Jersey a high proportion of AIDS cases are found among drug abusers who have shared needles presumably contaminated with infectious blood.

The first cases of AIDS were reported in Los Angeles in mid-1981 among five young homosexual men who were diagnosed originally with *Pneumocystis carinii* pneumonia, a disease commonly found in AIDS patients. Almost concurrently the first case of AIDS in New Jersey appeared in October, 1981. Subsequently, the number of cases in New Jersey and the United States has continued to increase rapidly producing considerable morbidity and mortality. Diagnoses of AIDS made retroactively continually increase its prevalence for the early years. Retroactive diagnosis produced a case of AIDS in New Jersey in July, 1980; that case was followed by two additional cases later in the year. At the present time AIDS is a uniformly fatal disease.

New Jersey's AIDS Surveillance Program within the newly formed AIDS Division compiles data on AIDS cases in New Jersey. The program has adopted the surveillance case definition used by the Centers for Disease Control (CDC). A reliably diagnosed disease must be present that is at least moderately indicative of an underlying cellular immunodeficiency in a person who has had no known underlying cause of cellular immunodeficiency, nor any other cause of reduced resistance reported to be associated with at least one of the opportunistic diseases present. This case definition reflects the rudimentary understanding of the virology, immunology, treatment and prevention of AIDS. Uncertainty exists about the definitive clinical indicators of the disease. No serological evidence is included in the definition. The definition also excludes cases of AIDS-related complex (ARC), although as tests on the presence of HIV become more widely applied, the ARC designation will no longer be needed. Future refinement of the case definition of AIDS will alter the current incidence and prevalence rates in the population. The currently reported cases of AIDS represent only a portion of its infection in the population.

Table A shows the most currently available data released by New Jersey's AIDS Surveillance Program on diagnosed cases and deaths of AIDS in New Jersey for 1985 and for 1986. These data reveal the increasing rate of AIDS cases and deaths that is occurring in New Jersey. The number of diagnosed cases for 1986 is approximately 57 percent higher than for the previous year. The rate of death is high and persons with diagnosed cases do not survive for long. Already 59 percent of all cases diagnosed in New Jersey have ended in death.

TABLE A
AIDS CASES AND DEATHS IN NEW JERSEY, 1985-1986

	Diagnosed	Deaths
1985	687	363
1986	1,079	653

Data in Table B have been reported by the Center for Disease Control. This table shows the total number of active AIDS cases identified nationally and the eight highest ranking states. As of December 22, 1986, 13,270 active cases of AIDS had been reported to the CDC from 50 States and the District of Columbia. The largest number of cases were reported by New York State, approximately one-third of all AIDS cases reported nationally. California had the second highest number of AIDS cases, and Texas had the third highest. Florida had the fourth highest. New Jersey ranked fifth with 799 cases or 6.0% of the AIDS cases reported throughout the country.

TABLE B
ACTIVE AIDS CASES REPORTED TO CDC
BY STATE OF RESIDENCE - AS OF DECEMBER 22, 1986

State of Residence	Number of Cases	Percent
New York	3,785	28.6
California	2,799	21.1
Texas	997	7.5
Florida	851	6.4
New Jersey	799	6.0
Illinois	364	2.7
Pennsylvania	307	2.3
Georgia	302	2.3
Remainder of U.S.	3,066	23.1
Total	13,270	100.0

Table 8 presents diagnosed AIDS cases and deaths in New Jersey by county of residence for both 1985 and 1986. The geographical distribution of cases is important for organizing health and social services and for identifying critical areas of exposure and contact. For both 1985 and 1986 AIDS cases were most prevalent in four (4) northeastern counties of the state: Hudson County with rates of 26.4 and 41.0 per 100,000 population for 1985 and 1986, respectively; Essex County with rates of 24.4 and 38.0; Passaic County whose rates were 13.9 and 19.1; and Union County with rates of 10.1 and 15.1 per 100,000 population. These four counties with some of the most populous areas in the state are where 66% of all AIDS cases reside. Death rates for AIDS were correspondingly the highest among these counties

The distribution of AIDS cases by sex and race shown in Table 9 did not change substantially in 1986 from the 1985 figures. There has been an increase in the proportion of women with AIDS, as well as an increase in those who are Hispanic. Approximately 80% of the diagnosed cases of AIDS in New Jersey occur among men. The CDC reports that nationally over 93% of AIDS cases are in men. Almost one-half of all AIDS cases in New Jersey occur among Blacks, while nationally 25% of all cases are Black. Nationally 60% of AIDS cases occur in Whites, while Whites in New Jersey constituted 37% of the AIDS population in 1986. In 1985 the highest percentage of AIDS cases appeared in Black males. In 1986 the highest percentages of AIDS cases existed almost equally in both white and black males (32.1% and 34.1% respectively). Less than 15% of the diagnosed AIDS cases occurred among Hispanics for both years.

Table 9 also shows AIDS deaths in New Jersey by both sex and race for 1985 and 1986. The distribution of AIDS deaths is similar to the distribution shown for diagnosed AIDS cases. From 1985 to 1986 the percentages of total AIDS deaths decreased among white men and increased among white women. Over 80% of all AIDS deaths occurred in men. More Blacks died than Whites during both years. In fact, the highest percentages of AIDS deaths for all race and sex groups occurred among Black males for 1985 and for 1986 (41% and 36% respectively). In 1985 50.4% of the deaths occurred in Blacks, 40.2% in Whites, 9.1% in Hispanics and less than 1% in other racial groups. In 1986, 47.8% of all AIDS deaths were among Blacks, 37.1% among Whites, 14.7% among Hispanics, and 0.5% occurred among other racial groups. The CDC reported the mean age of AIDS patients diagnosed before 1984 as 36.3 years. Thus there will be a sizable decrease in life expectancy, or sizable "years of potential life lost", for those groups most affected by AIDS.

The figures for AIDS cases and deaths shown in these tables underestimate case morbidity and mortality. Other persons may be infected with the HIV viruses or be experiencing the signs and symptoms of AIDS but not have identified themselves to the AIDS case surveillance unit. The long incubation period between infection with the retrovirus and diagnosis will lead to consistently underestimating the disease's prevalence on the population. A planned review of death certificates may reveal additional deaths due to AIDS that were not considered to be AIDS at the time of death.

TABLE-1

TUBERCULOSIS CASES AND DEATHS, NUMBERS AND RATES
PER 100,000 ESTIMATED POPULATION: 1962-1986

YEAR	ALL CASES		DEATHS

1981	7,407,643	2,096	28.3	606	8.2	500	6.7	22,998	310.5
1982	7,426,952	1,930	26.0	663	8.9	520	7.0	22,665	305.2
1983	7,467,973	2,088	28.0	823	11.0	578	7.7	22,075	295.6
1984	7,511,320	2,006	26.7	678	9.0	572	7.6	20,351	270.9
1985	7,560,997	2,284	30.2	760	10.1	548	7.2	19,751	261.2
1986	7,619,670	1,993	26.2	672	8.8	551	7.2	19,612	257.4

- 1) The sharp decrease in new cases of syphilis in 1972 reflects improved tabulation of data eliminating cases previously recorded in New Jersey or other states.
- 2) Total Cases includes Late and Late Latent, and Congenital Syphilis.

Accident Reports 1986

INTRODUCTION

Accidental death data for New Jersey have been collected and tabulated since 1968 through the use of the New Jersey Mortality reporting system. Accidental deaths are tabulated monthly and submitted to the National Safety Council as part of their overall reporting system. Data received from all the states are combined to prepare the National Safety Council's report, Accident Facts. Before the publication of this New Jersey accident report, no published summary of accidents for New Jersey had been released to the public. A number of special tables, however, were prepared and included in the prior releases of the New Jersey Public Health Reports.

The Accidental Death report includes all deaths regardless of the victim's state of residency. Accidental deaths relating only to New Jersey as the residence of the accident victim have been included in the Mortality report. This report of accumulated deaths provides an in-depth review of accidents by five major types of accidents reported by the National Safety Council. It also includes another grouping of accidents by their commonly referred to names and/or class, i.e., Motor Vehicles, Falls, Fires, Drowning, etc. Historical statistics have been compiled covering the period from 1972 to 1986 by subdivisions of cause and age groups. All tables are presented in aggregated form with individual identifiers removed.

STATISTICAL OVERVIEW

Total Accidental Deaths

The term "accidents" covers most deaths from violent occurrences. Deaths from homicides and suicides, however, are excluded as are deaths for which none of these categories apply and deaths in war operations.

Total accidental deaths in New Jersey regardless of the residence of the victim, increased in 1986 from the 1985 level of 2,294 to 2,353. This represents an increase of 2.6% over the year. Most of this increase can be accounted for by 104 additional motor vehicle accidents. Total accidental deaths at the national level increased in 1986 from the 1985 level of 92,070 to 95,640. This increase nationally represents a 3.9 percent increase in total accidental deaths. Motor vehicle deaths in the nation increased from 44,930 to 48,560.

New Jersey vs. National Accident Rate

In 1986, the New Jersey accidental death rate per 100,000 state residents was 30.9 up 8.4% from 28.5 in 1985. This rate is 22.2% lower than the national rate of 39.7 per 100,000 population for the same time period. An accident death rate for all accidents occurring in the State cannot be computed because there is no known way to include the out-of-state population base.

Motor Vehicle Accidental Deaths

Motor vehicle deaths included those deaths involving mechanically or electrically powered highway transport vehicles in motion (except those on rails) both on and off the highway or street. Fatalities occurring in the State as the result of motor vehicle accidents rose in 1986 by 10.2% from the 1985 level of 1,017 to 1,121. For the nation there was an increase of 8.1%. Of the 1,121 New Jersey deaths in 1986, 383 (34.2%) were the result of a collision with other motor vehicles; 272 (24.3%) were classified as pedestrian deaths; 158 (14.1%) deaths resulted from a collision with a fixed object; 115 (10.3%) were caused by noncollision; 36 (3.2%) were listed as "injury to pedal cyclist" deaths; 3 (.3%) deaths were the result of a collision with a railroad train; and 154 (13.7%) were classified as Other and Unspecified deaths. Of all the specified classifications of motor vehicle deaths, injury with pedal cyclist increased substantially in 1986 versus 1985 with an increase of over 157% (or 22 deaths). While the drivers of motor vehicles represent the majority of the deaths that resulted in this classification, the records show that one out of every four motor vehicle accident deaths was a pedestrian.

Accidental Deaths in the Home

This category of accidents resulting in deaths includes deaths in the home and on the premises to occupants, guests, and trespassers. Also included in this category are domestic servants, but other persons working on home premises are excluded. The year 1986 recorded 473 accidental deaths in the home. This is an decrease of 12.1% from the 1985 level of 538. The ranking of New Jersey accidental deaths in the home for 1986 is as follows: The large majority, 78.9% of accidental deaths in the home, occurred from falls, fires, and poisonings.

1986 ACCIDENTAL DEATHS IN THE HOME

Type	Number	Percent
Falls	135	28.5
Poisonings (gas excepted)	121	25.6
Fires	117	24.7
Drownings	33	7.0
Suffocation (ingested food or object)	14	3.0
Poisonings (by gases and vapors)	13	2.7
Suffocation (mechanical)	9	1.9
Firearms	2	0.4
Other and Unspecified	29	6.1
Total	473	100.0

Public Nonmotor Vehicle Deaths

Public accidents include deaths in public places or places used in a public way that do not involve motor vehicles. Most sports and recreational deaths are included in this category. Deaths in the course of employment are excluded. In 1986, there were 311 Public Nonmotor Vehicle deaths, an increase of 15.6% from the 1985 total. In New Jersey, drownings top the list with 67 (21.5%); in second place were falls with 57 (18.3%); air transport deaths followed with 20 (6.4%); and in fourth place were railroad deaths with 18 (5.8%). Falls and drownings are the areas of greatest concern in this classification of accidental deaths for they account for over one-third (39.9%) of the total.

At Work

Work related deaths are those which arise in the course of gainful employment regardless of where the accident occurs. Excluded from this category are work deaths to domestic servants and deaths occurring in connection with farm chores that are classified as home deaths. Sixty-nine (69) accidental deaths occurred in New Jersey's work settings in 1986 compared to 71 reported in 1985; this was a decrease of 2.8%. Major death rankings in the workplace in 1986 are: (1) Construction, 18 deaths (26.1%); (2) Manufacturing, 5 deaths (7.2%); (3) Agriculture, 3 deaths (4.3%). A multiple unspecified category included 36 deaths (52.2%).

Overall Deaths - In Any Location or Setting

Another perspective can be obtained on accidental deaths by combining types of deaths by cause regardless of location of the accident.

The classification of accidental deaths reported in Table 9 produced the following ranking from most to least frequent for 1986: (1) Motor Vehicles, (2) Falls, (3) Poisonings, (4) Fires, (5) Drownings, (6) Job Related, (7) Suffocations, (8) Air Transport, (9) Railroad-Not with Motor Vehicle, (10) Water Transport, and (11) Firearms. A breakdown of the causes of death by age groups is presented in this same table.

Age of Death Analyses

An analysis of accidental causes of death by age for 1986 shows that 60% of the motor vehicle accident deaths occur to persons between the ages of 15 and 44. On the other hand, 62% of the falls happen to those persons 65 years of age and over. In 1986 52% of the drownings occurred to individuals between the ages of 15 and 44. Over one-quarter (26.1%) of the deaths by suffocation were children four years of age or less (up from 9.5% in 1985); Deaths by railroad -- not with motor vehicles -- indicate that 66.7% were in the 15-44 age group. The number of deaths caused by fires were fairly evenly distributed among all age groups. However, in relation to population percentages children under 5 and adults aged 75 years and older suffered a disproportionately higher share of deaths.

The three age groups that had a higher total accidental death percentage in 1986 than in 1985 are: (a) 5-14 year olds, 4.5% vs. 3.8%; (b) 15-24 year olds, 19% vs. 18.7%; and (c) 25-44 year olds, 33.2% vs. 29% (especially because of motor vehicle fatalities).

NATIONAL TRENDS IN POPULATION GROWTH

Past Patterns of Change

The pattern of population change by age is essentially a reflection of the fluctuation in the number of births over time, modified by changes in levels of immigration and mortality. Large fluctuations in fertility occurred during periods such as the Great Depression in the 1930s and the baby boom beginning in 1946. After sustaining a level of almost 3 million in the early to middle 1920s, the number of births dropped to 2.3 million by 1933-34 and did not return to their old levels until World War II.

In 1946-47, the year following the demobilization of the Armed Forces, the number of births reached a new plateau of 3.9 million, an increase of roughly a million over the previous year. Although the birth rate began to drop in the 1950s, the number of births exceeded 4 million for 11 successive years from 1953 to 1964. Births peaked at 4.35 million in 1960-61, but in no year between 1946 and 1971 did the number of births fall below 3.5 million. With the fertility decline of the 1970s, the level of births dropped to 3.1 million in 1973-74, and only in the 1980s has the number risen above 3.5 million again.

The population in the younger age groups (5 to 13 years) and in school enrollment has reflected the long term decline in births since the middle 1960s. Elementary school enrollment plummeted during the 1970s as the population in this age range declined by 17 percent or 6 million from almost 37 million in 1970. This population has continued to decline moderately in the 1980s. With the rise in births since the middle 1970s, the population under 5 is growing again, so that stabilization and some small growth of the elementary school-age population can be expected soon. Constriction of the population aged 14 to 17 continues as the last of the baby boom generation passes through high school. That age group has declined by almost 8 percent since 1980, the largest decline of any age group. The college-age and young-adult population (18 to 24 years old), which grew enormously during the 1960s and 1970s as the baby boom cohort entered these decades, has been declining since 1981.

The fastest growing age group in the United States in the 1970s, aged 25 to 34, increased by 4.9 million or 13.3 percent from 1980 to 1985. This age group will continue to grow during the 1980s but at a greatly reduced rate. By 1984, the oldest cohort of the baby boom had entered the 35-44 year old age group, which has had the largest increase of any group since 1980 (6.0 million or 23.9 percent). This is the most rapidly growing age group whose growth will continue in the future as the baby boom generation approaches middle age.

The population aged 45 to 54 is beginning to decline as the small Depression cohort ages. The age group from 55 to 64, which is now growing slowly, will begin to decline in size when the smaller cohorts of the late 1920s and the Depression enter this age group. By contrast, the elderly population in the United States (65 years and over) continues to grow rapidly increasing as a group by 3.0 million or 11.7 percent since 1980. The continued aging trend in the population is reflected in the change in the median age. Between 1980 and 1983, the median age rose 0.9 years from 30.0 years to 30.9 years.

Although the general pattern of population change by age is approximately the same for Whites and Blacks, the Black population is growing more rapidly, which is apparent from the distinct racial differences in some age groups. The Black population under 5 years of age has shown significantly greater growth than the White population under 5. Similarly, each Black age group, with the exception of the 35 to 44 years and 65 years and over groups, exhibits either a larger increase or a smaller decrease than the comparable White age group. The overall effect is that the Black population grew by 5.3 percent compared with 2.5 percent for Whites between 1980 and 1983.

The Census of 1980

The 1980 census showed that dramatic changes took place in the social fabric of virtually every state during the 1970s. Shifts in family, household, and marriage patterns over the decade have altered the makeup of American society at the National, State, and local levels.

According to the 1980 census counts, the median age of the population increased to 30 years from the 28 year level reported in the 1970 Census. The increase has been attributed to declining fertility, aging of the "baby boom" cohorts, and increasing longevity of the population. Less than one-quarter of the population in 1980 was under 15 years of age and 11.3 percent were 65 years old and over.

The data for virtually all states point to faster growth of nonfamily households (one person or unrelated people in the same household) than for families, increases in smaller household size, and more families maintained by women with no husband present. These trends reflect a greater tendency of people to live alone, delay marriage, separate and divorce. While families still make up 73 percent of all households, this figure has decreased from almost 90 percent shown in the 1970 Census. The data also reveal variations in the composition of families among different race and Spanish origin groups.

NEW JERSEY POPULATION TRENDS

Overview

With the results of the 1980 Census of Population and Housing, New Jersey tabulated seven million plus inhabitants making it the ninth most populous state in the nation. With the highest density in the nation at 983.0 persons per square mile as of April 1, 1980, it had fifteen times the density of the United States and almost three times that of the Middle Atlantic region. Already, the most densely populated state in the nation, New Jersey has passed the 1,000 - person per square mile level (with a population density of 1,020.3 persons per square mile as of July 1, 1986). Rhode Island was a distant second at 924.1 persons per square mile as of July 1, 1986. State population density figures, while correctly stating the population to land ratio do not, however, reflect the whole picture. Density is not uniform within the State. It varies considerably from county to county and from municipality to municipality.

The southern counties of New Jersey (Salem and Cumberland), as well as those in the northwest (Hunterdon, Sussex, and Warren), have population densities under three hundred per square mile. These densities contrast markedly to the counties of Hudson and Essex which have upward of twelve and seven thousand persons per square mile respectively. It is in the State's northern area where the four largest cities are located and where the concentration of population is the greatest.

Growth Trends

During the decades of the 1950s and 1960s the State's population expanded rapidly, growing at an average annual rate of 2.3% from 1950 to 1960 and 1.7% from 1960 to 1970 compared to the national rates of 1.8% and 1.3%. The State's population "boom" came at the time when the Middle Atlantic states were experiencing far slower growth rates. The trend reversed, however, and has gripped the State since 1973. Population decreased during the 1973-1977 period. The average annual increase was only 0.2% for the decade compared with 0.9% for the United States. The net change for New Jersey between the Census period 1970-1980 indicated a 2.5% overall increase while the nation as a whole increased by 11.4%.

Source of Change

The population growth consists of two major components. The first is classified as Natural Increase and comprises births minus deaths. The second is termed Net Migration which is an inward movement of new residents minus outward movement. It is interesting to see how New Jersey's growth patterns relate to Natural Increase almost paralleling that of the United States, while net migration occurred from the north and central regions of the country to the warmer southern and southwestern regions.

A review of the State's birth rate shows that historically New Jersey had a lower birth rate than the United States. Birth rates have declined substantially in the past thirty years both nationally and in New Jersey. New Jersey's death rate was also slightly higher than the national average during the 1950s and early 1960s, but since the mid sixties the crude death rates have been similar. In 1985, New Jersey's death rate was higher than the national rate. The leading cause of death in both New Jersey and the nation as a whole continues to be heart disease, which in 1986 claimed 362.2 persons per 100,000 residents. Cancer, the second leading cause of death, accounted for 223.1 deaths per 100,000 New Jersey residents.

Net Natural Increase

With Net Natural Increase as the major component of population growth it is logical that births and deaths should have a strong influence on future growth and growth patterns within New Jersey. Nationally, as well as in the State, the net natural rate of increase has been falling since birth rates have declined faster than death rates. Moreover, New Jersey's net natural rate of increase has been below the national average for the past three decades because of a lower birth rate and a similar or higher death rate. From 1970 through 1984, for instance, New Jersey's annual net natural increase averaged about 0.47% compared to .98% for the United States. Nationally, however, the birth history showed a decrease from 1980 to 1984; the national rate moved from 15.9 to 15.8. The death rate in the U.S. remained constant at 8.8 deaths per 1,000 population in 1980 and 8.7 deaths per 1,000 population in 1986. In New Jersey the birth rate rose from 13.1 per 1,000 population in 1980 to 14.2 per 1,000 population in 1986 while the death rate remained constant (at 9.3 per 1,000 population in 1980 and in 1985). However, the death rate dropped to 9.4 per 1,000 population in 1986.

Migration Rate

The other factor influencing population growth, Net Migration, showed a movement from New York and Pennsylvania to New Jersey's growing suburbs during the 1950s and 1960s. New Jersey's average annual net migration rate of 1.13% for 1950-1960 was nearly seven times the nation's 0.17% average annual rate. The State's 1960-1970 annual rate of .78%, likewise, was considerably higher than the national annual average, which remained at 0.17%. This influx of population explains most of New Jersey's rapid growth from 1950 to 1970.

New Jersey's in-migration slowed in the seventies, especially during the recession periods of 1970 and 1974/75. In fact, more people left the State than entered with an average net migration rate of about 0.2% annually compared to a national gain of 0.2%. This reversal in the State's net migration trend explains to a degree the slowing and the decline that has taken place within the State in the late seventies. A slowed rate of out-migration was confirmed by the 1980 Census. New Jersey's net in-migration rate was 0.3%. While this 0.3% is lower than the national rate of 1.0% for the same time period, it is a marked reversal from the net out-migration New Jersey was experiencing in the 1970s.

Intrastate Differences

The total New Jersey population increased by only 3.5% between 1980 and 1986. In 1986, births outnumbered deaths by approximately 37,000. Internal shifts were similar as in past years and not unlike demographic trends found nationwide. Older cities continued to lose not only their manufacturing base but their residents who moved to the suburbs. Suburbia remained relatively stable in density of settlement, but continued to move outward with a greater radius from center cities as new "exurbs" grew. In relatively rural counties of southern New Jersey, especially near the shore, large retirement communities were established.

The State's six largest cities (Newark, Jersey City, Paterson, Elizabeth, Trenton and Camden) remained virtually unchanged between 1980 and 1986 ranging from an average annual percent increase of +0.02% in Elizabeth and +0.01% in Paterson and a 0.65% decrease in Newark. Between 1970 and 1980 the counties with the greatest population decrease of 7 to 990 were three urban counties, Essex, Hudson and Union. With its new gambling casinos Atlantic City is showing some reversal of its former economic decline. Although employment has increased, total resident population has not changed.

The most notable population changes in this State in the decade between 1970 and 1980 were the growth of four relatively rural counties. Hunterdon's population increased by 25%; Cape May's by 38%; Sussex by 50%; and Ocean County by 66%. Three of these four counties (Hunterdon, Cape May and Sussex) were among the five counties with the least population in the State in both 1970 and 1980. In two of these counties, Cape May and Ocean, growth can be attributed to a large increase in retirement communities. In Hunterdon, the age structure of the population in 1980 was very similar to the State as a whole. In Sussex, the age structure shows a larger number of younger families. The age structure in each of the counties and in the State is presented in Table 3.

Since 1980, Ocean County is estimated to have grown by the largest amount: approximately 48,000 persons or 13.8%. Cape May had the second highest rate

between 1980 and 1986 of 2.0% per year, which is greater than half of its annual growth rate for the period 1970-80. By contrast, the three largest counties in the State, Bergen, Essex, and Hudson, are the only ones that have declined in numbers.

Racial Composition

As in the past, the racial composition of the New Jersey population resembles closely that of the United States. The 1960 Census data reported 91.3% of New Jersey's population was white compared to 88.6% for the United States. By 1980 the white population represented 83.2%. New Jersey's black population increased from 8.5% to 16.8% of the population over the past twenty-years from 1960 to 1980. In the nation the increase for the same period was from 10.5% to 11.7%.

Age Distribution

The State's population is slightly "older" than the nation as a whole. The age distribution of the State's population has changed markedly over the years. The decline of the birth rate and the decreasing death rate have decreased the percentage of "future workers" in the population, while enlarging the top end of the age structure. In 1960, 29.0% of New Jersey's population was under fifteen years of age, but by 1970 this group accounted for only 27.8% of the population. By 1980 those under 15 represented 21.4%, and by 1984 those under 15 years of age represented 20.2%. The disparity increases for the portion of the population under ten. In 1960, 20.3% of the population was ten and under with only 17.9% in 1970, 13.2% in 1980, and 12.8% in 1984. At the upper end of the age distribution, the share of population 65 and over has increased from 9.1% in 1960 to 9.7 in 1970. The 1980 census shows a further increase to 11.7%, and in 1986 persons over age 64 represented 12.9%. The New Jersey trends parallel those of the United States as a whole and could have serious implications in the next ten to twenty years as a declining working-age population will have to support an increasing number of elderly people. The impact on our medical establishment will be profound as well.

Marriage and Divorce

During the seventies marriages decreased with the exception of 1972 and 1973 which gave an indication of an upturn that did not materialize until later. The bottom was reached in 1977, and since then an upturn has occurred. Marriage rates have increased in recent years even though women have increasingly chosen careers over marriage or postponed marriage to establish a career. Nationally, marriage rates have decreased from their peak at 11.1 per 1,000 population in 1950 to 10.8 in 1980. The State's marriage rate which was a low 6.5 in 1959 rose to 7.6 in 1980 and reached 8.3 in 1983 and 1984. In 1985, and 1986 the marriage rate in New Jersey declined to 8.1. Divorce rates have increased significantly in both New Jersey and the nation during the past thirty years. New Jersey's 1985 rate of 3.7 divorces per 1,000 population was more than 2.7 times the 1970 rate.

1986 POPULATION

Overview

As of July 1, 1986, New Jersey's population was estimated at 7,619,670 -- up by 254,989 or 3.5% from the census count on April 1, 1980. Although substantially less than the U.S. gain of 6.4%, New Jersey outpaced the other seven most populous states in the Northeast and North Central Regions, including New York and Pennsylvania.

New Jersey's Comparative Growth

Although New Jersey's annual rate of population increase since 1980 (0.58% per year) was less than half of the national gain (1.08% per year), state growth was about twice the increase shown in New York. Pennsylvania showed virtually no change at all. Of the eight largest states (over 5 million) in the Northeastern and North Central Regions, not only did New Jersey lead in the percent increase, but it was second only to New York in absolute growth since 1980.

A primary reason for New Jersey's growth was its positive net migration; that is, fifty-nine thousand more people moved into New Jersey than moved out from 1980 to 1986. New Jersey was the only state among the "Top Eight" in the Northeast and North Central Regions with this distinction.

SOURCES OF DATA

Vital Events

Birth, death, fetal death, and marriage certificates are the basic source documents used for collecting data on vital events occurring to New Jersey residents during the calendar year. Birth, death, and fetal death certificates are completed by hospital personnel, physicians, and funeral directors. Marriage certificates are completed by the person officiating. Copies of the certificates are available from the Bureau of Vital Statistics.

The cut-off date for the submission of vital events data contained in this report is May 1 of the following year. Any data pertaining to an event that occurred during the calendar year, but for which a certificate was filed or changed after May 1, are not included.

Births and deaths of New Jersey residents that occurred in another state are included in this report. The inclusion of these data is made possible by an agreement among all registration areas in the United States for exchange copies of certificates. No marriage certificates are exchanged under this agreement, however.

Population

The population data used in this publication are based in part on data collected by census enumerators during the latest decennial Census of Population and Housing, conducted by the U.S. Bureau of the Census. Every person and housing unit is questioned regarding certain basic demographic information such as age, race, and relationship. Population data for each year following the decennial census are based on the annual estimates released by the NJ Department of Labor, Office of Demographic and Economic Analysis. They assemble data about births and deaths that are provided by the Center for Health Statistics, along with migration data, to update the population figures.

Abortions

The New Jersey Abortion Surveillance Program is a health monitoring system conducted by the Center for Health Statistics within the New Jersey Department of Health. Reporting forms are completed by licensed abortion facilities and are coded and processed by the Center on a monthly basis.

Morbidity

There are two sources of morbidity data in New Jersey. Certain communicable diseases are required by law to be reported to the Department. Various programs throughout the Department of Health collect these data. Each program forwards a copy of their data to the Center for Health Statistics on an annual basis. The other source of morbidity data is hospital discharge data forms. The medical discharge abstract data forms are designed by the Center and completed by all licensed hospitals, general and specialty, for every inpatient service episode. The format of these forms emphasizes clinical information, not cost or charges. These data are submitted to the Center quarterly and are analyzed annually.

Divorces

Divorce and annulment data are compiled from transmittal documents that are received from records maintained by the Office of the Administration of the Courts. Copies of these records are forwarded to the Center for Health Statistics annually for inclusion in this report.

Accidents

Only accidents resulting in deaths are covered in this report. The causes of fatal accidents are obtained from the death certificates.

DATA QUALITY

Vital Events

The quality of these data is directly related to the completeness and accuracy of the information contained on the vital certificates. The NJ/DOH works to ensure that the information received is as complete and accurate as possible; it maintains two major program operations related to improving the quality of information received on vital certificates.

The query program is a system used to follow up with local registrars, hospital personnel, funeral directors, and/or physicians, concerning incomplete or conflicting information. The follow-back contact is usually done by telephone and is based both on a manual and computer editing procedure.

The field program improves vital certificate data quality by educating the participants in the vital registration system, e.g., hospital personnel, funeral directors, local registrars, and physicians, of the uses and importance of vital statistics data. For example, seminars are conducted with direct participation of these individuals and various associations. Also, the NJ/DOH field representative makes site visits when problems with registration relating to a particular area or institution are discovered.

The National Center for Health Statistics (NCHS) monitors New Jersey's coding of birth and death data. NCHS has established a two percent upper limit for coding difference involving any one item, with the exception of cause of death. A five percent limit is established for this item because of the complexity of the coding process. For additional information regarding coding quality levels for New Jersey or other states contact the National Center for Health Statistics, Technical Services, Division of Vital Statistics, Research Triangle Park, North Carolina.

Population

While it is impossible to completely eliminate error from an operation as large and complex as the decennial census, the U.S. Bureau of the Census attempts to control errors during collection and processing operations through record checks and re-checks, post-enumeration follow-back, quality control checks during processing, and the installation of special coding procedures for nonresponses to questions on the census questionnaire. For further details regarding the quality controls on U.S. Census data, refer to Starsinic, Donald E., "Evaluation of Population Estimation, Procedures for Statistics, 1980: An Interim Report." Current Population Reports Series P-25, No. 933, issued June 1983, page 2.

The NJ/DOH controls the quality of the birth and death data supplied to the NJ/DOL as described above. Contact the NJ/DOL for further details regarding their control over migration data quality.

Abortions

Abortion data are collected only from clinics, not private physicians. Thus, only a portion of all legal abortions in New Jersey are included. The quality of these data are maintained by computer edits performed on all data submitted and by clerical review of all records for obvious errors. Queries are made to the providers to correct the abortion information prior to issuing this report.

Morbidity

Reportable diseases are monitored for completeness by the Communicable Disease Control Services Program under the Division of Epidemiology and Disease Control. A manual tracking system is in place that checks and double checks all information received by the Communicable Disease Control Unit. Any errors detected are corrected before the data are released. All data are actual counts.

Two measurements are used in assessing the accuracy and quality of the medical discharge abstracts data. The first relates directly to the data contents of the data tapes, which are evaluated for completeness, consistency, and overall levels of error. All errors detected are reviewed and levels of severity established in terms of rates of error relative to all data that are received. The second measure tracks the completeness and correctness of coding. This measure is based upon a direct comparison of the records maintained by the facility to the abstract data submitted to the Department.

Divorces

Divorce data are obtained directly from the New Jersey Department of Justice Court Records Summary Statistics. Records are processed and run through an extensive set of edit checks by the NJ/DOJ. No further checks on data quality are performed by the Center for Health Statistics on divorce data obtained from the NJ/DOJ.

GEOGRAPHIC CLASSIFICATION

Vital Events

Vital events can be classified geographically in two ways, by place of residence or place of occurrence. Throughout this report state, county and minor civil division (MCD) where the person affected resides is used to classify vital events. For example, the usual residence of the mother, in the case of a newborn, or the decedent, in the case of death, is used. Fetal deaths and infant deaths, in cases where the child was never discharged from the hospital, are classified by the residence of the mother. While occurrence statistics have both administrative value and statistical significance, residence statistics are by far the more useful tool when constructing health indices for planning and evaluation purposes. For instance, the vital statistics residence data are used to determine the "natural increase" component of the state's population estimates provided by the NJ/DOL. The only exception to the use of place of residence for geographical classification in this report relates to marriages and divorces. County breakdowns of these data describe where the marriage or divorce took place.

It should be noted that the allocation of vital events by place of residence is not always straightforward. For various reasons, a person's statement of their residence may be incorrect or incomplete. For example, mailing addresses often differ from the actual residence. When the mailing address of an unincorporated or local name place is given as the place of residence, it may prove impossible to allocate the event to the correct MCD. Postal zip codes are used for cross reference when the correctness of residence is in question. Note, this problem affects primarily MCD classification. Resident counts for the state and counties are substantially correct.

Population

The error associated with residence is almost nonexistent in the 1980 Census of Population and Housing data, since this census involved on-site enumeration of both population and housing units. County boundaries legally defined and in effect as of January 1, 1980 were recognized in the 1980 census. Census data are also available from the NJ/DOL Office of Demographic and Economic Analysis for geographic areas not represented in this publication, such as census tracts and enumeration districts. Townships that are incorporated in the state of New Jersey are included as MCDs.

Abortions

City and zip code of the abortion recipient are recorded on the reporting form submitted to the Center for Health Statistics. No verification is performed on the patient's report. A postal zip code notification program has been installed in the computer/edit phase to verify the MCD.

Since abortion surveillance began, 78% to 85% of all reported abortions performed at in-state facilities have been on New Jersey residents. The NJ/DOH is unable at this time to obtain detailed data on New Jersey residents receiving an abortion in other states or at physician's offices. The data compiled by the Center for Health Statistics include only those data on residents receiving abortions at licensed facilities within the State.

Morbidity

Control is maintained over the geographic location coding for both reportable diseases and medical discharge abstracts data. Systems have been developed to insure correct reporting of resident codes. In addition, a postal zip code verification program has been installed in the computer edit phase of data processing to identify mistakes.

DEFINITION OF RATES

Absolute counts of health-related events do not readily lend themselves to analysis and comparison between years and various geographic areas because of population size differences. In order to compare the health status of populations that differ in size, the absolute number of events is converted to a relative number, such as the probability of living or dying expressed as a rate, a ratio, or an index. This conversion is made by relating the crude number of events happening to the living population at risk in a particular area at a specified time to the size of the same population.

In interpreting the causes of differences in vital statistics rates, consideration should be given to the many ways in which two or more groups differ, for example, demographic differences such as age, sex, and ethnicity. Further adjustment of the crude or overall rates presented in this report may be required to properly describe why rates of births or disease differ between populations the reader may wish to compare.

DESCRIPTIVE STATISTICS:
RATES, RATIOS, PROPORTIONS, AND INDICES*

- A. **RATE:** A rate measures the frequency of occurrence of some particular event. A rate is of the form:

$$\frac{x}{y} \times k$$

where

- x = number of times an event has occurred during a specific interval of time,
- y = number of persons exposed to the risk of the event during the same interval, and
- k = some round number (100, 1,000, 10,000, 100,000, etc.) or base, depending upon the relative magnitude of x and y.

1. **MORBIDITY RATES:** Morbidity rates measure the frequency of illness within specific populations. Time and place must always be specified. The most commonly used morbidity rates include point prevalence, period prevalence, incidence, and attack rate as shown in Table E.

- a. **PREVALENCE:** Prevalence measures the frequency of all current cases of disease (old and new) and is of two types:

(1) **POINT PREVALENCE:** Point prevalence measures the frequency of all current cases of a disease (old and new) at a given instant in time.

(2) **PERIOD PREVALENCE:** Period prevalence measures the frequency of all current cases of disease (old and new) for a prescribed period of time.

- b. **INCIDENCE:** Incidence measures the rapidity with which a disease occurs or the frequency of addition of new cases of a disease. These new cases of a disease occur either through onset of the disease on current members of the population or by immigration of persons already ill into the population. Incidence is always calculated for a given period of time.

- c. **ATTACK RATE:** An attack rate is an incidence rate usually expressed as a percent, used for particular populations, and observed for limited periods of time, as in an epidemic.

*NOTE: This section and the accompanying Table E are from: Vital and Health Statistics: Techniques of Community Health Analysis, published in 1978 by the Center for Disease Control, U.S. Department of Health and Human Services.

2. **MORTALITY RATES:** Mortality rates measure the frequency of deaths within specific populations and are calculated for a given time interval and place. Several general and specific formulae are used to describe mortality as shown in Table E.
3. **NATALITY RATES:** Natality rates measure the frequency of births (birth rates) and the probability of births (fertility rates) within specific populations and are calculated for a given time interval and place. Some frequently used natality rates and ratios are shown in Table E.

- B. **RATIO:** A ratio is the expression of the relationship between a numerator and denominator that may involve either an interval in time or may be instantaneous in time. The ratio is of the form:

$$x : y \quad \text{or} \quad \frac{x}{y} \quad x \quad k$$

where

- x = number of events or items counted and not necessarily a portion of y,
- y = number of events or items counted and not necessarily a population of persons exposed to the risk, and
- k = a base, as in the case of a rate, but usually 1 or 100 for the purpose of expressing ratios.

- C. **PROPORTION:** A proportion is an expression in which the numerator is always included in the denominator, and the values vary between zero and one. A proportion may be expressed as a percent by multiplying by 100.

- D. **INDEX:** An index is the best available approximation to a true rate. An approximation is needed when the number at risk (denominator) cannot be counted directly. Then, some other variable that can be counted is substituted to estimate the number at risk.

For example, in order to calculate a maternal mortality rate, we should, strictly speaking, divide the number of deaths assigned to deliveries and complications of pregnancy, childbirth, and the puerperium by the total number of pregnancies occurring in a specified time interval. Since we are unable to count the total number of pregnancies, we substitute the number of registered live births; this figure serves as an estimate of the number of pregnancies. The resulting maternal mortality rate is therefore not a rate at all in the strict sense, but is nevertheless a useful index which gives an impression of the risk of dying associated with pregnancy.

TABLE E
 FREQUENTLY USED RATES, RATIOS, PROPORTIONS, AND INDICES
 USED FOR DESCRIBING NATALITY, MORBIDITY, AND MORTALITY

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
<u>NATALITY</u>				
1.	<u>Birth Rate</u> Crude; specific for age of mother, sex of child, socioeconomic status, etc.	Number of live births reported during a given time interval	Estimated mid-interval population	1,000
2.	<u>Fertility Rate</u>			
	(a) <u>Theoretical Purposes</u>	Number of live births reported during a given time interval from mothers aged 15-44 years	Estimated number of women in age group 15-44 years at mid-interval	1,000
	(b) <u>Current Usage</u> Crude; specific for age of mother, race, socio-economic status, etc.	Number of live births reported during a given time interval	Estimated number of women in age group 15-44 years at mid-interval	1,000
3.	<u>Low Birth Weight Ratio</u> Crude; specific for age of mother, race, socioeconomic area, etc.	Number of live births under 2,500 grams (or 5½ lbs.) during a given time interval	Number of live births reported during the same time interval	100

TABLE E (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
<u>MORBIDITY</u>				
4.	<u>Incidence Rate</u>			
	Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.	Number of new cases of a specified disease reported during a given time interval	Estimated mid-interval population	Variable: 10^x where $x = 2, 3,$ $4, 5, 6,$
5.	<u>Attack Rate</u>			
	Crude by cause; specific for age, race, sex, socio- economic area, etc.	Number of new cases of a specified disease reported during a specific time interval	Total popula- tion at risk during the same time interval	Variable: 10^x where $x = 2, 3,$ $4, 5, 6,$
6.	<u>Point Prevalence Rate (Ratio)</u>			
	Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.	Number of current cases, new and old of a specified disease existing at a given point in time	Estimated popu- lation at the same point in time	Variable: 10^x where $x = 2, 3,$ $4, 5, 6,$
7.	<u>Period Prevalence Rate (Ratio)</u>			
	Crude by cause; specific for age, race, sex, socio- economic area, stage of disease, etc.	Number of current cases, new and old, of a specified disease occurring during a given time interval	Estimated mid-interval population	Variable: 10^x where $x = 2, 3,$ $4, 5, 6,$

TABLE E (Continued)

<u>MORTALITY</u>				
8.	<u>Crude Death Rate</u>			
	Crude; specific for age, race, sex, socioeconomic area, etc.	Total number of deaths reported during a given time interval	Estimated mid-interval population	1,000
9.	<u>Cause-specific Death Rate</u>			
	or			
	<u>Cause of Death Rate</u>			
	Crude by cause; specific for age, race, sex, socio-economic area, etc.	Number of deaths assigned to a specific cause during a given time interval	Estimated mid-interval population	100,000
10.	<u>Cause-Specific Death Ratio</u>			
	or			
	<u>Cause of Death Ratio</u>			
	or			
	<u>Proportional Mortality Ratio</u>			
	Crude by cause; specific for age, race, sex, socio-economic area, etc.	Number of deaths assigned to a specified cause during a given time interval	Total number of deaths from all causes reported during the same interval	100 or 1,000
11.	<u>Case Fatality Rate (Ratio)</u> <u>Death-to-Case Ratio</u>			
	Crude; specific for age, race, sex, socio-economic area, etc.	Number of deaths assigned to a specified disease during a given time interval	Number of new cases of that disease reported during the same time interval	100

TABLE E (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
12.	(a) <u>Fetal Death Rate I</u>	Number of fetal deaths of 28 weeks or more gestation reported during a given time interval	Number of fetal deaths of 28 weeks or more gestation reported during the same time interval plus the number of live births occurring during the same time interval	1,000
	(b) <u>Fetal Death Rate II</u>	Number of fetal deaths of 20 weeks or more gestation reported during a given time interval	Number of fetal deaths of 20 weeks or more gestation reported during the same time interval plus the number of live births occurring during the same time interval	1,000
13.	(a) <u>Fetal Death Ratio I</u>	Number of fetal deaths of 28 weeks or more gestation reported during a given time interval	Number of live births reported during the same time interval	1,000
	(b) <u>Fetal Death Ratio II</u>	Number of fetal deaths of 20 weeks or more gestation reported during a given time interval	Number of live births reported during the same time interval	1,000

TABLE E (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
14.	(a) <u>Perinatal Mortality Rate I</u>	Number of fetal deaths of 28 weeks or more gestation reported during a given time interval plus the reported number of infant deaths under seven days of life during the same time interval	Number of fetal deaths of 28 weeks or more gestation reported during the same time interval plus the number of live births occurring during the same time interval	1,000
	(b) <u>Perinatal Mortality Rate II</u>	Number of fetal deaths of 20 weeks or more gestation reported during a given time interval plus the reported number of infant deaths under 28 days of life during the same time interval	Number of fetal deaths of 20 weeks or more gestation reported during the same time interval plus the number of live births reported during the same time interval	1,000
15.	<u>Infant Mortality Rate</u>	Number of deaths under 1 year of age reported during a given time interval	Number of live births reported during the same time interval	1,000
	Crude; specific for race, sex, socioeconomic area, birth weight, cause of death, etc.			

TABLE E (Continued)

No.	Description of Measure	Numerator (x)	Denominator (y)	Expressed Per Number At Risk (k)
16.	<u>Neonatal Mortality Rate</u>			
	Crude; specific for race, sex, socioeconomic area, birth weight, cause of death, etc.	Number of deaths under 28 days of age reported during a given time interval	Number of live births reported during the same time interval	1,000
17.	<u>Postneonatal Mortality Rate</u>			
	(a) <u>Theoretical Purposes</u>	Number of deaths from 28 days of age up to, but not including, 1 year of age, reported during a given time interval	Number of live births reported during the same time interval less the number of deaths under 28 days of age	1,000
	(b) <u>Current Usage</u>			
	Crude; specific for race, sex, socioeconomic area, cause of death, etc.	Number of deaths from 28 days of age up to, but not including, 1 year of age, reported during a given time interval	Number of live births reported during the same time interval	1,000
18.	<u>Maternal Mortality Rate</u>			
	Crude; specific for age of mother, race, socioeconomic area, etc.	Number of deaths assigned to causes related to pregnancy during a given time interval	Number of live births reported during the same time interval	10,000

**SELECTION OF STATISTICAL FORMULAS USED IN THIS REPORT FOR COMPUTING
BIRTH, DEATH AND MORBIDITY RATES**

Crude Birth Rate - see Table E, No. 1.

Fertility Rate - see Table E, No. 2(a).

Crude Death Rate - see Table E, No. 8.

Infant Mortality Rate - see Table E, No. 15.

Neonatal Mortality Rate - see Table E, No. 16.

Fetal Death Rate - see Table E, No. 13(b).

Perinatal Mortality Rate - see Table E, No. 14(b).

Maternal Mortality Rate - see Table E, No. 18.

Specific Cause-of Death-Rate - see Table E, No. 9.

Age-Specific Death Rate - Expressed per 100,000 population in a specified age group,

$$\frac{\text{No. of Deaths in a Specific Age Group}}{\text{Midyear Population Estimate for the Same Age Group}} \times 100,000.$$

Morbidity Rate - Expressed per 100,000 (10,000 or 1,000) population,

$$\frac{\text{No. of Reported Cases of a Given Disease}}{\text{Midyear Population Estimate}} \times 100,000 \text{ (10,000 or 1,000),}$$

which is analogous to a period prevalence rate covering only cases reported to the NJ/DOH.

DEFINITIONS

<u>ABORTION</u>	premature expulsion or removal from the uterus of the products of conception (the embryo or nonviable fetus).
<u>ACCIDENT</u>	that occurrence in a sequence of events which usually produces unintended injury, death or property damage.
<u>ACCIDENT TYPE</u>	describes the occurrence leading to injury or property damage.
<u>AGE-SPECIFIC MORTALITY RATE</u>	the number of deaths of a given age group per 100,000 estimated persons in that age group usually expressed as an annual rate.
<u>AGENCY OR AGENT</u>	the principal object such as tool, machine or equipment in the accident and is usually the object inflicting injury or property damage.
<u>APGAR SCORE</u>	composite measure used to evaluate the newborn infant's general condition. Apgar scores are given one and five minutes after birth. Heart rate, respiratory, effort, color, muscle tone and reflexes are checked and evaluated. Each factor receives a score of 0, 1, or 2 and the sum of the five values is the overall score. A score of ten is optimum.
<u>ASSOCIATED CAUSE OF DEATH</u>	condition other than the underlying cause of death which may have contributed to the death.
<u>BIRTH RATE</u>	the number of live births per 1,000 population.
<u>BIRTHWEIGHT</u>	weight of fetus or infant at time of delivery (normally recorded in pounds and ounces or in grams).
<u>CAUSE GROUP</u>	a summary of deaths resulting from or cases of, related diseases as defined by the International Classification of Diseases adapted for use in the United States, published by the U.S. Department of Health, and Human Services; usually specified by a series of 3-digit codes; i.e. 140-208 malignant neoplasms.
<u>DAY</u>	(motor vehicle accidents) is the time interval between sunrise and sunset.

DEATH RATE

the number of deaths per 100,000 population.

DEATH FROM ACCIDENT

a death which occurs within one year of the accident.

DELIVERIES

live births plus reported fetal deaths.

DISABLING INJURY

an injury causing death, permanent disability, or any degree of temporary total disability beyond the day of the accident.

ESTIMATED POPULATION

the estimated number of persons in a given group based on the latest census data and adjusted for annual births, annual deaths and net migration.

FATAL ACCIDENT

an accident which results in one or more deaths within one year.

FERTILITY RATE

the number of live births to women aged 15-44 per 1,000 women in this age group, usually expressed as an annual rate.

FETAL DEATH

death prior to the complete expulsion or extraction from its mother of a product of conception; the fetus shows no signs of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

FETAL DEATH RATE

the number of fetal deaths occurring in the twentieth week of gestation or later (required by law to be registered as fetal deaths) per 1,000 live births, usually expressed as an annual rate.

FIRST TRIMESTER

first twelve weeks of pregnancy, as determined by the history given by the patient considered in conjunction with the physician's estimation of length of pregnancy by clinical examination of the size of the uterus (NJAC 8:40-4.1).

HOME

a dwelling and its premises within the property lines, including in addition to the usual single-family dwellings and apartment houses, duplex dwellings, boarding and rooming houses and seasonal cottages. Excluded from homes are barracks, dormitories, and resident institutions.

HOMICIDE

the act of one person who kills another, includes deaths from injuries purposely inflicted by other persons, deaths from injuries resulting from intervention by law enforcement officers and deaths caused by legal execution.

HOSPITAL

health care facility licensed as a hospital in accordance with the statutes of New Jersey.

HYSTERECTOMY

excision of the uterus.

HYSTEROTOMY

incision of the uterus to remove the fetus before viability.

ILLEGITIMATE BIRTHS

a birth to an unwed woman, or to a woman whose husband did not father the infant.

ICD-9 CODE

a listing of disease classification known as the "Ninth Revision International Classification of Diseases Adapted for Use in the United States," published by the United States Department of Health and Human Services, used in the statistical coding and tabulation of specific disease morbidity and mortality.

IMMATURE BIRTH

a live birth weighing 2,500 grams (5 Lbs. 8 oz.) or less.

INCIDENCE RATE

incidence is the number of occurrences of an event, such as the number of new cases of tuberculosis.

incidence rate is expressed in terms of the population in which the event occurs within a specified time period.

incidence rates are usually expressed as representing the cases per 100,000 population per year.

INFANT DEATH

death occurring to live born individual of less than 1 year of age.

INFANT MORTALITY RATE

the number of infant deaths per 1,000 live births, usually expressed as an annual rate.

LEGITIMATE BIRTH

a birth to a married woman whose husband fathered the infant.

LIVE BIRTH

a live birth is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration and pregnancy, which after such separation, breaths or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

MATERNAL DEATHS

those wherein the physician has designated a maternal condition as the underlying cause of death.

MATERNAL MORTALITY RATE

the number of maternal deaths per 10,000 live births, usually expressed as an annual rate.

MINOR CIVIL DIVISION

New Jersey Minor Civil Divisions (MCD) are legally incorporated political subdivisions and are the local level of civil government. The various cities, municipalities, townships, villages, and towns encompass all areas of the state. They are mutually exclusive, i.e., no one MCD overlaps another, even though it may surround another.

MORTALITY

the number of deaths per a specified number of people.

MOTOR VEHICLE

any mechanically or electrically powered device (except one moved by human power), not operating on rails, upon which or by which any person or property may be transported upon a land highway. The load on a motor vehicle, or trailer attached to it, is considered part of the vehicle. Tractors and motorized machinery are included while self-propelled in transit or used for transportation. Also included are motor scooters, motorized bicycles and snowmobiles.

MOTOR VEHICLE ACCIDENT

any accident involving a motor vehicle in transport (in motion, in readiness for motion, or on roadway, but not parked in a designated parking area) that results in death, injury or property damage.

MOTOR VEHICLE TRAFFIC ACCIDENT

a motor vehicle accident which occurs on a trafficway -- a way or place, any part of which is open to the use of the public for purposes of vehicular traffic.

MOTOR VEHICLE NONTRAFFIC ACCIDENT

any motor vehicle accident which occurs entirely in any place other than a trafficway.

NEONATAL

of, relating to, or affecting the newborn and especially the human infant during the first month of life.

NEONATAL DEATH

live born infant who dies before completing four weeks (28 days) of life.

NEONATAL MORTALITY RATE

as used in this text, the number of deaths of infants under 28 days of age per 1,000 live births, per year.

NIGHT

(motor vehicle accident) is the time interval between sunset and sunrise.

NONFATAL INJURY ACCIDENT

an accident in which at least one person is injured and no injury terminates fatally.

NONMOTOR VEHICLE

any vehicle other than a motor vehicle, except a scooter, wheelchair, roller skates, ice skates, skis, baby carriage, and similar means of transportation; persons using these latter means of transportation are considered pedestrians.

OCCURRENCE DATA

data classified by place where event occurred, regardless of the person's place of residence (marriages, divorces).

OUTPATIENT ABORTION FACILITY

licensed health care facility other than a hospital in which abortion procedures are performed.

OUT-OF-WEDLOCK BIRTH

birth wherein there is no marital tie between mother and father.

PEDACYCLE

a vehicle propelled by human power and operated solely by pedals, excludes mopeds.

PEDESTRIAN

any person who is not in or upon a motor vehicle or non motor vehicle (see definition of motor vehicle) included as pedestrians are persons using a coaster wagon, child's tricycle, roller skates, etc. Excluded are persons boarding, alighting, jumping or falling from a motor vehicle in transport.

PERINATAL

of, relating to, or affecting the fetus and the newborn, especially the human infant during the first month of life.

PERINATAL MORTALITY RATE

number of deaths of infants less than 28 days of age (Neontal Deaths), and registered fetal deaths of 20 weeks or more gestation per 1,000 live births plus registered fetal deaths.

PERMANENT DISABILITY

(synonymous with permanent impairment) includes any degree of permanent impairment of the body, such as amputations, permanent impairment of vision and other permanently crippling nonfatal injury ranging from the permanent suffering of a joint or a finger amputation, to permanent, complete crippling.

PREMATURE BIRTHS

products of conception weighting less than five pounds, nine ounces (2,500 grams or less) at delivery or expulsion.

PROPERTY DAMAGE ACCIDENT

an accident which results in property damage, but in which no person is injured.

PROSTAGLANDIN

a class of drugs used to induce a second-trimester abortion; usually injected into the uterine cavity by a needle inserted through the abdominal wall or introduced as a vaginal suppository.

PUBLIC ACCIDENT

any accident other than motor-vehicle that occurs in the public use of any premises, includes deaths in recreation (swimming, hunting, etc.) transportation except motor-vehicle, public buildings, etc. and deaths from widespread natural disasters even though some may have happened on home premises. Excludes accidents to persons in the course of gainful employment.

RACE

(as relates to birth certificate) race for mother, father or as stated on the certificate. Race of child is determined from the race of the parents.

RACE-SPECIFIC MORTALITY RATE

number of deaths in a given race group per 100,000 estimated population in that ethnic group.

RATE

a rate measures the frequency of occurrences of some particular event. A

rate is of the form: $\frac{x}{y} \times k$

Where

x = number of times an event has occurred during a specific interval of time.

y = number of persons exposed to the risk of the event during the same interval.

k = some round number (100; 1,000; 10,000; 100,000; etc.) or base, depending upon the relative magnitude of x and y.

RESIDENCE

usual place of residence of person to whom event occurred. For births and fetal deaths, residence is defined as the mother's place of residence.

RURAL

(for motor vehicle reporting) includes places of less than 5,000 inhabitants, except those classified as urban by the U.S. Census Bureau.

SALINE INSTILLATION

second-trimester method of induced abortion usually performed at or after 16 weeks of pregnancy by instilling a concentrated salt solution into the amniotic sac by a needle inserted through the abdominal wall.

SECOND AND THIRD TRIMESTERS

pregnancy of 13 or more weeks as determined by the history given by the patient, the physician's findings or clinical examination of the size of the uterus before the abortion, and/or the size of the fetus as examined after the abortion (NJAC 8:40-4.1).

SEX-SPECIFIC MORTALITY RATE

number of deaths of males/females per 100,000 estimated males/females in the population.

SHARP CURETTAGE

dilation of cervix and removal of the product of conception by a semi-sharp spoon-shaped instrument.

SUCTION CURETTAGE

dilation of cervix and removal of the product of conception by a vacuum method.

SUICIDE

the act or an instance of taking one's own life voluntarily and intentionally.

TEMPORARY TOTAL DISABILITY

an injury which does not result in death or permanent disability, but which renders the injured person unable to perform regular duties on one or more full calendar days after the day of the injury.

TRIMESTERS

1st - first 12 weeks of pregnancy
2nd - second 12 weeks of pregnancy
3rd - period after first 24 weeks of pregnancy

UNDERLYING CAUSE OF DEATH

that condition giving rise to the chain of morbid events leading to death, or the circumstances of the accident or violence that produced the fatal injury.

URBAN

(for motor vehicle reporting) includes place of 5,000 or more inhabitants, and the towns, townships and other areas classified as urban by the U.S. Census Bureau.

WORK HOURS

are the total number of hours worked by all employees. They are usually compiled for various levels, such as an establishment, a company or an industry. A work hour is the equivalent of one employee working one hour.

WORK INJURIES

(including occupational diseases) are those which arise out of and in the course of gainful employment regardless of where the accident occurs. Excluded are work injuries to domestic servants and injuries occurring in connection with farm chores which are classified as home injuries.

WORKERS

are all persons gainfully employed, including owners, managers, other paid employees, the self-employed, and unpaid family workers, but excluding domestic servants.

**CENTER FOR HEALTH STATISTICS
DIVISION OF RESEARCH, POLICY AND PLANNING
NEW JERSEY DEPARTMENT OF HEALTH**

**NEW JERSEY
STATE AND COUNTY POPULATION ESTIMATES
BY
AGE, SEX, AND RACE
JULY 1, 1986**

These estimates should be used only for
statistical purposes as applied to health data.

NOTE: These age, sex, and race levels were developed using the provisional Official State Estimates for July 1, 1986 which were released by the Department of Labor in September, 1987. The age, sex, and race levels contained in this report are not official estimates and are intended for statistical use by health professionals in computation of morbidity and mortality rates by age, sex, and race characteristics and in projecting ranges of "need".

DIVISION OF RESEARCH, POLICY AND PLANNING
NEW JERSEY DEPARTMENT OF HEALTH**

NOTES ON DATA AND ESTIMATING METHOD ESTIMATES BY AGE, SEX, AND RACE

The age, sex, and race estimates in this report were developed for Health Statistics Purposes Only. While these estimates are considered crude, they represent the only age, sex, and race data available for July 1, 1986. Using county controls, these estimates were generated through the Department of Labor's "Official State July 1, 1986 Population Estimates,"¹ which include values for total population by county and residents aged 5 years and under, 5 through 17, 18 through 64, and 65 and over.

To generate the age, sex, and race proportionate shares for New Jersey and its 21 counties, linear interpolation was performed between the 1982 estimate values released by Richard Irwin at the U.S. Bureau of the Census, and the 1990 Population Projections information developed from ODEA Economic - Demographic Model prepared by the Department of Labor in November, 1986. These 1990 population projections did not present age, sex, and race information for Cape May, Hunterdon, Sussex, and Warren Counties because of small values, especially for the nonwhite population. To generate values included herein for Cape May, Hunterdon, Sussex, and Warren Counties, the Department of Labor provided the Health Department, with the unpublished projections of race and sex, with the understanding that the projection not be released, but reserved for internal use only.

While these estimates attempt to account for births, deaths, aging, and migration factors in the population through the use of linear interpolation between 1982 estimates and 1990 projections (as described above) and statistical control to 1986 provisional county estimates, they are only very crude estimates. They are, however, the only data available in the absence of any hard indicators of the population age distributions by race and sex that could be more accurately ascertained through use of administrative records (i.e., Medicare, school enrollment, driver's license registration, taxation, etc.). These crude estimates were generated and are intended for use only by health professionals for statistical purposes, such as computation of morbidity and mortality rates and health planning modelling of "need" for health care services by age, sex, and race at the county level.

Users should be aware that the 1986 county base population level used to generate these data may not agree with individual breakdowns and that county values may not add to state values because of rounding.

NEW JERSEY DEPARTMENT OF HEALTH

HOSPITALIZATION IN NEW JERSEY

Overview

All acute care, general and specialty hospitals are required by regulation to submit patient care information to the NJ/DOH in hospital discharge abstract form annually. These data are combined and edited; incomplete or inaccurate records are returned to the hospitals for correction. Thus, processing times required to assemble these data delay the reporting of this information for up to 18 months. The results provided in this section will lag by one year other data presented in the Health Statistics report. Thirteen items from the discharge abstracts are covered below. Information about seven other items may be obtained by contacting the Center for Health Statistics. Data for two calendar years are presented for comparison purposes.

Total Discharges

During calendar year 1985, there was a total of 1,258,083 discharges of patients from licensed New Jersey hospitals. This was a slight increase of 1.4% over 1984. It should not be assumed, however, that total discharges represent only one admission per patient. Patients are sometimes readmitted because of complications that arise after discharge or because of a different illness. Of the total discharges, 947,016 or 75.3% represent one admission and discharge for each patient. This was a slight increase of 0.2% over 1984. Readmissions associated with a different diagnosis numbered 237,459 cases or 18.9% of all discharges in 1985, up 6.4% from 1984. On the other hand, 5.9% or 73,608 cases in 1985 were readmissions with the same principal diagnosis - up 2.2% from the 1984 level.

Referral Source

The question has often been asked--How do patients get into a hospital (by type of referral source)? The principal method is by direct physician's referral. This represented 56.43% of all cases in 1985, compared to 63.7% for 1984. The second highest referral source was through the emergency room--30.1% for 1985 as compared to 31.3% for 1984.

Admission Class

There was virtually no change in proportion from 1984 to 1985 in Admission Class - the circumstances under which the patient entered the hospital. Emergency and Urgent represented 49.7% - a decrease of 2.9% from 1984 with Elective showing 50.3% - a decrease of 3.0% from 1984.

Sex

Of the total 1,258,083 discharges during 1985, 41.9% were of male patients and 58.1% of female. The ratio of female to male requiring hospitalization has always been higher for women because of maternity admissions. The difference between 1984 and 1985 is not significant with the ratios approximately at the same level.

Race

Looking at patients with regard to race we find that white had the highest percentage with 75.5% and black reporting 14.9%. Hispanics were counted at 6.3%. None of the other race categories registered above the 1% level.

Age

A complete breakdown has been tabulated for each individual age. However, to give a better overview an age cohort grouping for 5-year intervals was made for comparison purposes. A review of the ages based on five year groups indicates that the 5 and under group, which includes infants, presents the highest percentages (12.5%). Table 1 exhibits a slight but distinct shift toward increasing hospitalizations of older persons from 1984 to 1985, as well as the characteristic maternity use rate rise for the ages 20 through 40.

Primary Services

Of the 99 designated classifications of clinical services provided for hospitals the NJ/DOH has mapped them into 10 major primary service groupings. This mapping or grouping permits comparisons in like categories, i.e., Medicine, Surgery, etc. In comparing the 1984 data with the 1985 we find a slight difference between some of the categories but they remain at approximately the same level for all practical purposes. Newborn was one area to show a major decrease going from 5.4% in 1984 to 2.9% in 1985. Orthopedics was the other with a significant decrease going from 6.1% in 1984 to 5.4% in 1985. Medicine represented 44.1%; followed by Surgery, 21.7% and Gynecology, 5.5%. Pediatrics accounted for 8.3%, Psychiatry, 1.9%, Obstetrics, 9.5%, and Dental, 0.6%.

Discharge Status

During 1985, the largest majority of patients were routinely discharged, 92.1%. Transfers to another facility or institution represented 3.9%. There were, however, 1.1% that left against medical advice. Discharge status listed as expired was reported at approximately the same level of 2.8% as recorded for 1982.

Transfer Destination

When a patient is discharged they either go home, expire, or are referred to another facility. By far the majority of patients, about 96.3%, are recorded with no transfer destination, indicating that they have gone home. This was true for 1985 which showed a slight decrease for the 1984 figure of 96.8%. Long Term Care facilities, the second highest group, represented approximately 1.5% as opposed to 1.3 in 1984 with Other Acute Care Facilities at 1.0% (12,596), an increase from the 1984 total of 10,998 or 0.9%. Likewise Home Health Agencies indicated only about one-half of a percentage (5,667) for 1985, an increase from the 1984 level of 4,870 or .4%.

Primary Payor

The financial health of the hospital sector is determined to a great extent by who is paying for health services. Each third party payor has a unique schedule of reimbursement--in terms of what type of care is covered, the proportion of charges covered and the speed with which reimbursement occurs. Blue Cross had the largest number of people enrolled who used hospitals in 1985 at 32.6%, with Medicare running second at 28.9%. Commercial (or private) insurance companies were third with 14.6% and Medicaid fourth with 9.5%.

Principal Causes for Hospitalization

In 1985 the four principal causes for hospitalization were single live births (99,098), delivery in a normal case (26,266), cataract (23,612), and heart failure (21,530). In 1985 the fifth and sixth causes, namely other acute and subacute forms of ischemic heart disease (20,877) and acute myocardial infarction (18,330) remained unchanged. Therefore, the rank order of the first six principal causes of hospitalization was the same as in 1984, except for the reversal of third and fourth places. Other and unspecified after care was in seventh place in 1985. This caused Hernia (17,431) to drop to eighth place in 1985. Of the top ten principal causes for hospitalization in 1984 all made the 1985 top ten ranking.

DIVISION OF RESEARCH, POLICY AND PLANNING
NEW JERSEY DEPARTMENT OF HEALTH**

Suicides 1986

BACKGROUND

Durkheim (1951) was the first social researcher to do an in-depth study of social factors which affect risk of suicide. He observed that suicide rates were higher among Protestants than Catholics, higher among the divorced than among the married, and higher during periods of political lethargy than during crisis. Later Dublin (1963) pointed out that older white males, urban dwellers, and the divorced and widowed had markedly elevated risks of suicide. In Dublin's own words: "We have seen that certain environmental factors - economic conditions, city life, religious affiliations, social customs, and laws and traditions - influence the prevalence of suicide. It also differs markedly in various groups of the world's population with relatively high rates in some areas, low rates in others, and striking differences in the two sexes, in the several age periods, and in the principal races into which mankind is divided."

New Jersey had the lowest suicide rate of any state in the nation in 1980 according to the Centers for Disease Control Suicide Surveillance report issued March 1985: 7.4* suicide deaths per 100,000 population in New Jersey compared to the highest in Nevada (22.9 per 100,000) population. New Jersey's suicide rate has increased by 14.9% in the seven year period 1980 to 1986 to a rate of 8.7 per 100,000 population in 1986.

A Youth Suicide Prevention Act (N.J.P.L. 1985, Chapter 195, also N.J.S.A. 30:9A-12) established suicide intervention programs in the schools and crisis intervention programs for adolescents and their families. Information on services available may be obtained from:

*New Jersey official statistics show a suicide rate of 7.8 per 100,000 population in 1980.

INTRODUCTION

Suicide is a serious public health problem, but less so in New Jersey than nationally. In 1980 suicide was the 13th ranking cause of death in New Jersey (among persons of all ages) and the 10th ranking cause of death nationally. In 1986 suicide ranked as the 11th leading cause of death in New Jersey and the 8th leading cause of death nationally. While suicide is a concern at every age (beyond 1 year) its rank as a leading cause of death is highest among New Jerseyans aged 15-24, where it is listed as the third leading cause of death. Suicide drops steadily as a leading cause of death from increasing ages to 20th place for persons above age 65 (Table 1) in New Jersey.

New Jersey's rate of suicides per 100,000 population has risen from 7.8 to 8.7 between 1980 and 1986, but New Jersey's suicide rate is far below that of the U.S.: 13.1 per 100,000 persons in 1986 (Figure 1 and Table 2).

White males consistently have the highest suicide rates of any race and sex category (Figure 2 and Table 3). Nonwhite males have the second highest rates, followed by white females and nonwhite females. Rates have risen in all four race-sex groups over the period from 1980 to 1986. However, the rate for nonwhite males after rising from 8.1 per 100,000 persons to 11.5 in 1985 dropped to 7.1 in 1986.

Figure 2
Suicide Rates Per 100,000 Population

Race/Sex for NJ Residents: 1980-1986

TRENDS BY AGE

Nationally, suicides at young ages were of such concern that a public health objective was formulated: "By 1990, the rate of suicide among people 15-24 should be below 11 per 100,000." New Jerseyans have been below the objective for each of the seven years studied, but the rate rose from 7.9 to 9.5 per 100,000 between 1983 and 1984 (Table 4) but reversed direction dropping to 9.1 and 8.6 in 1985 and 1986, respectively.

Suicide rates generally tend to increase with age (Figure 3 and Table 4). Between 1983 and 1984 there was an increase in suicide rates for each age group, except those over 65. However, between 1985 and 1986, there was a decrease in rates for each age group except those over 65 which remained constant. In 1986, New Jersey's suicide rate for persons aged 65 and over was 12.9 per 100,000 population compared to 24.1 per 100,000 population nationally. According to Grollman (1971), the elderly commit suicide the most of any age group, but attempt suicide the least. According to Busse and Pfeiffer (1969) the impact of retirement, especially for men, of physical decline, or somatic illness are among the speculated reasons why older people take their lives. Loss of a mate is well known to increase the risk of suicide (Parkes, 1969; MacMahon and Pugh, 1965); cancer diagnosis may as much as double the risk (Marshall, J.R., 1983).

Of the 127 geriatric (65 and above) suicides in New Jersey in 1986, 91 (or 71.7%) were white males; methods of lethality for white males aged 65 and over tended to be firearms (44 or 34.6%) and hanging (31 cases or 24.4%).

Adolescent suicides (Table 5) were the highest in New Jersey in 1985 with 55 cases compared to 47 in 1984. The median age among teenage suicides showed fluctuations over the 7 years studied ranging from 17.6 years in 1983 to 16.9 years in 1984. In New Jersey in 1986 the suicide rates for persons aged 1-14 and aged 15-24 were .6 and 8.6 per 100,000 persons (compared to national rates of .6 and 12.2 per 100,000 respectively).

Median ages for persons who died of suicide by race and sex over the seven-year period are shown in Table 6. Males tended to commit suicide at younger ages than females; nonwhites tended to show less of an age differential based on sex than whites and tended to commit suicide at younger ages than whites of the same sex. A complete age distribution by sex and race is shown in Table 7 for 1986 cases.

TABLE-4

SUICIDE BY AGE GROUP

*1 Female aged 25-44 for whom race is unknown.

METHODS OF LETHALITY

Method of suicide from 1980 to 1986 is shown in Table 8. The most frequently employed methods were firearms and hanging, strangulation, and suffocation. Among poisonings (24.0% of all suicides in 1986) solid or liquid substances increased in use over the period 1980 to 1986 from 8.7% to 13.0%, while gas poisonings decreased (from 13.4% to 11.0%).

Variations in method by race and sex for suicides committed in 1986 are shown in Table 9. Firearms and hangings were the most frequent methods of injury for white males. Hangings and firearms were the most frequent for nonwhite males. For females of both racial groups solid or liquid poisonings were most frequent, followed by hangings.

Methods also vary with age with firearms more frequently used among adolescents (40.9% of teenage suicides compared to 33.1% of all suicides in 1986). Hanging (ICD-9 code E953) was also more frequent among teenagers (34.1% of teenage suicides occurred by this method of injury in 1986); hangings represented 30.2% of all suicides in 1986.

* Total includes one female death, race unknown ICD code E950.

SEASONALITY

Suicides were more likely to occur in February, March, April, May and June (for females), and February, March, and May through August (for males). Seasonal trends are shown in Table 10. A ratio of seasonality was used to compare the actual number of suicides each month to the expected number (adjusted for the length of the month). Seasonal variation differed between sexes (Figure 4) with January, July and December being infrequent times for suicides among females and November being a more frequent time for females than males; seasonal variation was much greater for females than males.

Figure 4
Seasonality of Suicides, By Sex

FOR NEW JERSEY RESIDENTS 1980 TO 1986

RESIDENCE

The resident suicides by age and sex are shown for New Jersey counties and principal municipalities in 1984 on Table 11. Counties with the highest suicide rates were Gloucester (12.3 per 100,000 population) and Atlantic (11.6 per 100,000 population) compared to Sussex (3.3 per 100,000 population) and Burlington (5.5 per 100,000 population) which were the lowest county rates (Table 12). Rates of change between 1986 and 1980 were computed, but care should be taken in interpretation because of the small number of cases at the municipal level.

METHODOLOGICAL ISSUES

Suicides in this report are those deaths identified as having cause-of-death codes E950-E959 from the International Classification of Diseases, ninth revision (ICD-9).

Suicide statistics based on death certificates probably understate the true number of suicides for several reasons (as stated by the CDC Violence Epidemiology Branch):

- 1) Inadequate information on which to make a determination of suicide as the cause of death.

"Without an explicit communication by the victim that the death was self-inflicted, the death might be erroneously ruled as homicide, an accident, or as undetermined. In other circumstances, there may be either conscious or unconscious attempts to obscure information necessary to make the determination of suicide, as in the case of a family deliberately withholding or unconsciously denying information to avoid stigmatizing themselves or the victims."

- 2) Certifier bias or error.

"The certifier may be influenced in recording an accurate certification of suicide because of pressures brought to bear by family or friends of the suicide victim. Also, error in judgment may occur on the part of the certifier because of inadequate criteria or standards for making a determination of death by suicide given a particular set of circumstances. That is, based on the same set of information, two certifiers may rule differently as to whether the death should or should not be determined to be suicide."

- 3) No death certificate filed on the victim.

"Some suicide deaths might not be recorded if the bodies are never found. This bias may be more significant for specific methods of suicide, e.g., drowning after jumping from a high bridge."

If suicides are misclassified on death certificates, these deaths are most likely to be reported under accidental deaths as pointed out by Douglas in 1967. From Holdings and Barraclough's comparative studies, the underestimate of the true suicide rate reflected by official statistics may be as much as 22%.
